JOHN DORY (JDO)

(*Zeus faber*)
Kuparu

**1. FISHERY SUMMARY****1.1 Commercial fisheries**

John dory are taken mainly as a bycatch of the trawl and Danish seine fisheries. In recent years, around 50–65% of the total reported catch has been taken in JDO 1, and around 20% taken in JDO 2. Recent reported landings by Fishstock are shown in Table 1, while the historical landings and TACC values for the three main JDO stocks are depicted in Figure 1.

The increase in JDO 1 landings after 1986–87 is largely attributed to increased targeting of John dory by trawl and Danish seine. The TACC in JDO 1 was exceeded (slightly) in 1994–95, but in the following years landings steadily decreased, reaching a low of 440 t in 2002–03. Landings increased to 549t in 2005/06 but have since declined to 365t. It is estimated that during the 1990s about 10–20% of the annual JDO 1 landings were taken in FMA 9, mainly as bycatch in fisheries targeting snapper and trevally. Landings from the eastern part of JDO 1 (FMA 1) are taken primarily in target fisheries for John dory and snapper. However, since 1990 there has been a steady trend of increased target fishing directed at John dory and decreased landings of this species from the snapper fishery.

Annual landings in JDO 2 have never exceeded the TACC and in the mid 90s, were around 50% of the TACC in each year (Figure 1). From 1999–00 to 2002–03 landings were above 200 t, but in recent years landings have decreased, being below 150t since 2005/06.. Landings from JDO 2 are considered to be approximately equally split between FMAs 2 and 8. Substantial proportions of John dory landings are taken as bycatch in target trawl fisheries for jack mackerels in FMA 8, and as tarakihi and red gurnard bycatch in FMA 2.

Landings from JDO 7 increased markedly after 1999/2000, as a result of increasing abundance. JDO 7 is taken largely as a bycatch by FMA 7 trawl fisheries. The JDO 7 TACC has been increased three times since 2003/04 and is currently 150t (Table 1).

* FSU data.

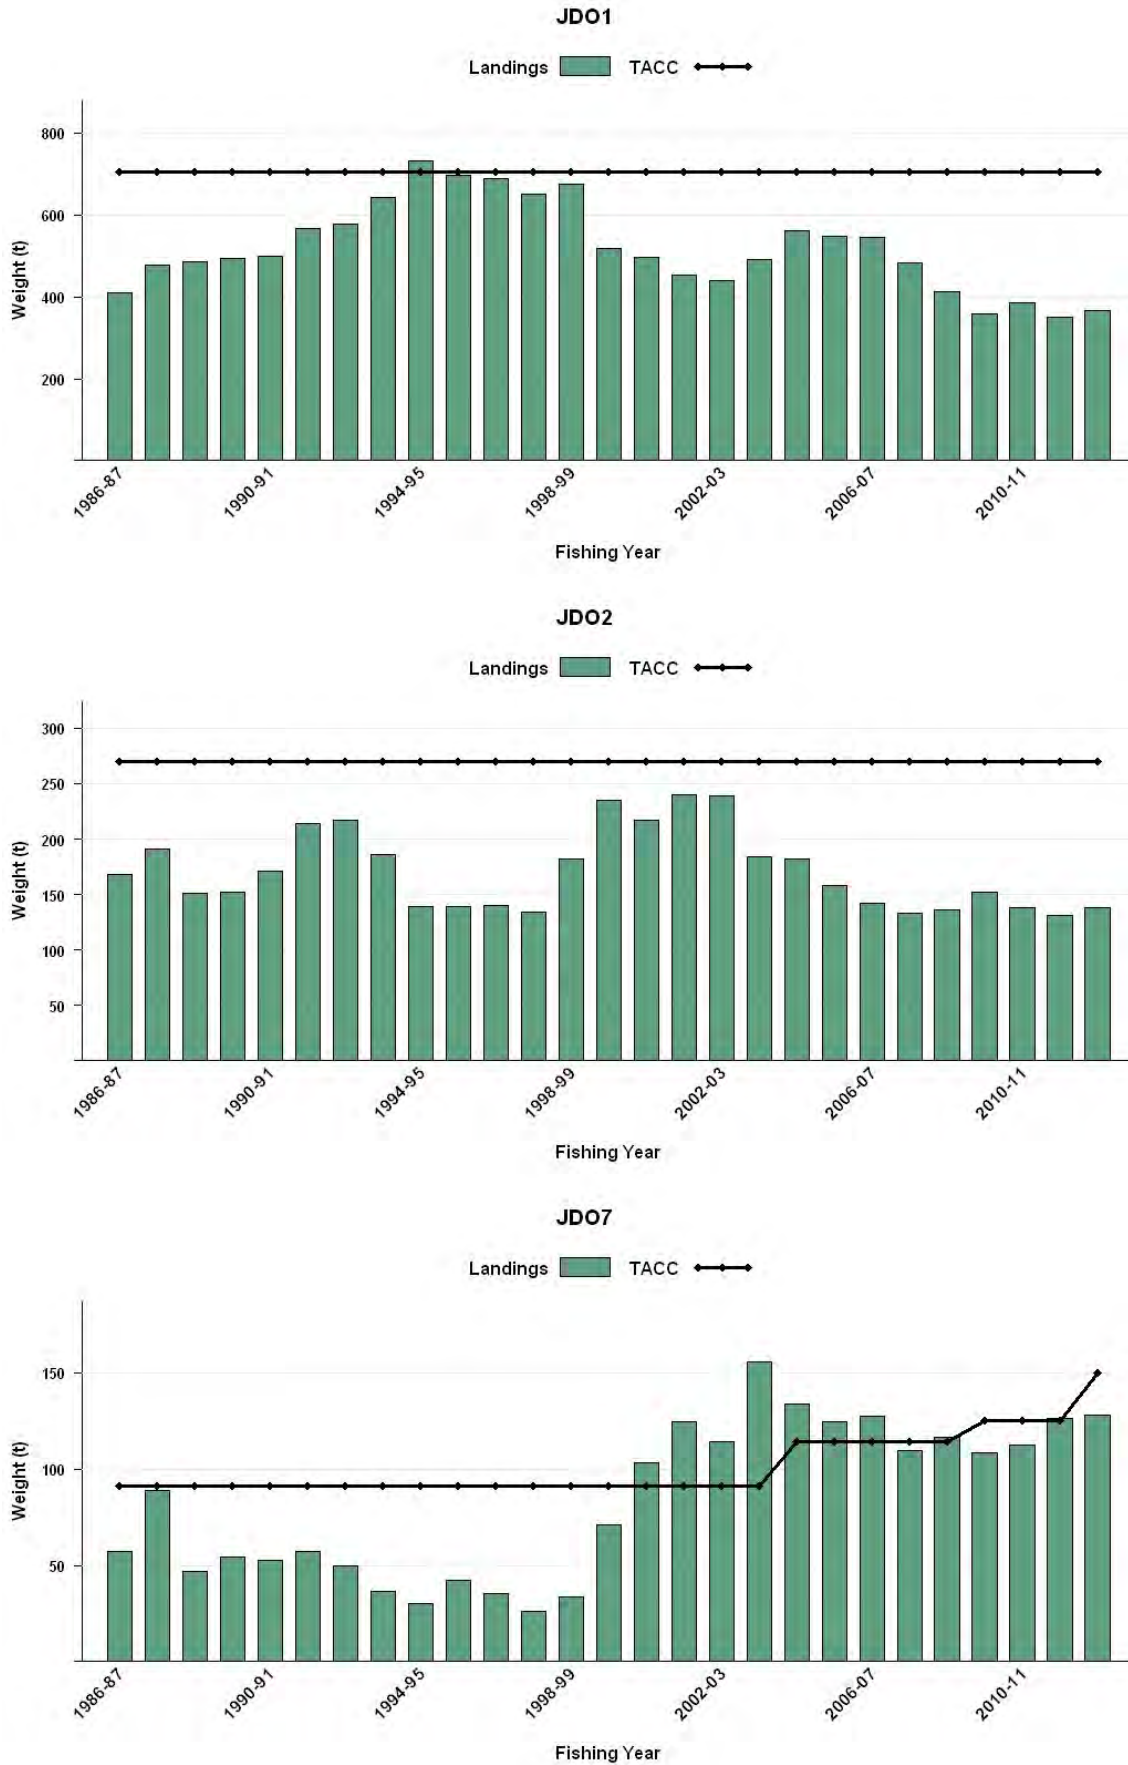

Figure 1: Historical landings and TACC for the three main JDO stocks. From top left: JDO 1 (Auckland East), JDO 2 (Central East), and JDO 7 (Challenger).

JOHN DORY (JDO)

Overall the majority of John dory catch is reported in the snapper bottom trawl fishery (16%), followed by the John dory bottom trawl (14%) and the tarakihi bottom trawl fisheries (14%). Danish seine accounts for the second largest John dory catch across fishing methods (Figure 2).

Catches of John dory in JDO 1 are predominantly taken through bottom trawl in the snapper (23%), John dory (19%) and trevally (10%) target fisheries. Danish seine, bottom pair trawl and bottom longline comprise the remaining John dory catch by fishing method (Figure 3). John dory catch in JDO 2 are taken predominantly by bottom trawl targeting tarakihi (30%) and gurnard (25%), with mid-water and setnet fishing methods comprising the remainder of catch (Figure 4). John dory in JDO 7 is predominantly caught by bottom trawl targeting flatfish (25%), barracouta (23%) and tarakihi (18%) (Figure 5). Throughout the North Island, the trawl and Danish seine fisheries targeting John dory take the majority of their catch targeting snapper (33%) followed by the John dory target fishery (23%) (Figure 6). No data were available for JDO setnet fisheries in the South Island.

Figure 2: A summary of the proportion of landings of John dory taken by each target fishery and fishing method. The area of each circle is proportional to the percentage of landings taken using each combination of fishing method and target species. The number in the bubble is the percentage. BT = bottom trawl, DS = Danish seine, BPT = bottom pair trawl, BLL = bottom longline (Bentley et al 2012).

Figure 3: A summary of the proportion of landings of JDO 1 taken by each target fishery and fishing method. The area of each circle is proportional to the percentage of landings taken using each combination of fishing method and target species. The number in the bubble is the percentage. BT = bottom trawl, DS = Danish seine, BPT = bottom pair trawl, BLL = bottom longline (Bentley et al 2012).

Figure 4: A summary of the proportion of landings of JDO 2 taken by each target fishery and fishing method. The area of each circle is proportional to the percentage of landings taken using each combination of fishing method and target species. The number in the bubble is the percentage. BT = bottom trawl, MW = mid-water, SN = setnet (Bentley et al 2012).

Figure 5: A summary of the proportion of landings of JDO 7 taken by each target fishery and fishing method. The area of each circle is proportional to the percentage of landings taken using each combination of fishing method and target species. The number in the bubble is the percentage. BT = bottom trawl, MW = mid-water (Bentley et al 2012).

Figure 6: A summary of species composition of the reported trawl and Danish seine catch in trips targeting John dory off the North Island. Catch is expressed as the percentage by weight of each species calculated for all trawl and Danish seine trips (Bentley et al 2012).

1.2 Recreational fisheries

John dory is an important recreational species in the north of New Zealand. They are caught using line fishing methods, predominantly on rod and reel with some longline catch.

1.2.1 Management controls

The main method used to manage recreational harvests of John dory is daily bag limits. Fishers can take up to 20 John dory as part of their combined daily bag limit in the Auckland and Kermadec, Central, and Challenger Fishery Management Areas.

1.2.2 Estimates of recreational harvest

There are two broad approaches to estimating recreational fisheries harvest: the use of onsite or access point methods where fishers are surveyed or counted at the point of fishing or access to their fishing activity; and, offsite methods where some form of post-event interview and/or diary are used to collect data from fishers.

The first estimates of recreational harvest for John dory were calculated using an offsite approach, the offsite regional telephone and diary survey approach. Estimates for 1996 came from a national telephone and diary survey (Bradford 1998). Another national telephone and diary survey was carried out in 2000 (Boyd & Reilly 2005). The harvest estimates provided by these telephone diary surveys (Table 2) are no longer considered reliable.

In response to the cost and scale challenges associated with onsite methods, in particular the difficulties in sampling other than trailer boat fisheries, offsite approaches to estimating recreational fisheries harvest have been revisited. This led to the development and implementation of a national panel survey for the 2011–12 fishing year. The panel survey used face-to-face interviews of a random sample of

JOHN DORY (JDO)

New Zealand households to recruit a panel of fishers and non-fishers for a full year. The panel members were contacted regularly about their fishing activities and catch information collected in standardised phone interviews. Note that the national panel survey estimate does not include harvest taken on recreational charter vessels, or recreational harvest taken under s111 general approvals. Recreational catch estimates from the national panel survey are given in Table 2.

Table 2: Recreational harvest estimates for John dory stocks. The telephone/diary surveys ran from December to November but are denoted by the January calendar year. The national panel survey ran through the October to September fishing year but is denoted by the January calendar year. Mean fish weights were obtained from boat ramp surveys (for the telephone/diary and panel survey harvest estimates).

Stock	Year	Method	Number of fish	Total weight (t)	CV
JDO 1	1996	Telephone/diary	49 000	87	0.09
	2000	Telephone/diary	129 000	227	0.23
	2012	Panel survey	28 863	36	0.13
JDO 2	2000	Telephone/diary	9 000	16	0.43
	2012	Panel survey	2 000	3	0.33

1.3 Customary non-commercial fisheries

No quantitative information is available on the current level of Maori customary non-commercial catch.

1.4 Illegal catch

No quantitative information is available.

1.5 Other sources of mortality

No quantitative information is available.

2. BIOLOGY

John dory are widespread, being found in the eastern Atlantic Ocean, the Mediterranean Sea and around New Zealand, Australia and Japan. They are common in the inshore coastal waters of northern New Zealand, and to a lesser extent in Tasman Bay, to depths of 50 m. In the Hauraki Gulf, adults move to deeper waters during summer, and occasional feeding aggregations occur during winter.

John dory are serial spawners (spawning more than once in a season). There appears to be substantial variation in the time of spawning in New Zealand, with spawning occurring between December and April on the northeast coast. The eggs are large and pelagic, taking 12–14 days to hatch. Initially John dory grow rapidly with both males and females reaching 12 to 18 cm standard length (SL) after the first year. From the second year onwards females grow faster than males and reach a greater maximum length. Females mature at a size of 29 to 35 cm SL and in general, larger females mature earlier in the season and are more fecund. Males mature at 23 to 29 cm SL.

M was estimated using the equation $M = \log_e 100/\text{maximum age}$, where maximum age is the age to which 1% of the population survives in an unexploited stock. Using a maximum observed age of 12 years, M was estimated to equal 0.38. Biological parameters relevant to the stock assessment are shown in Table 3.

Table 3: Estimates of biological parameters of John dory.

3. STOCKS AND AREAS

In 2012 the stock structure of John dory was reviewed (Dunn & Jones 2013). The approach evaluated patterns in the distribution of catch and CPUE, research survey biomass trends, location of spawning and nursery grounds, size and age compositions, and anecdotal information from the fishery.

John dory have been caught around most of the North Island and the northern South Island, indicating that the QMA boundaries are not biologically appropriate. The analysis suggested five stocks around New Zealand: (1) Hauraki Gulf and east Northland; (2) Bay of Plenty; (3) west coast North Island; (4) southeast North Island; and (5) northern South Island.

Spawning fish and nursery grounds are found in all five stocks. In addition, on the east coast North Island, CPUE analyses support the separation of the Hauraki Gulf, Bay of Plenty, and Hawkes Bay fisheries, and research trawl survey biomass estimates had different trends in Hauraki Gulf and the Bay of Plenty. Very few John dory are found south of Hawkes Bay on the southeast North Island, providing a gap between the east and west coast components of JDO 2. There is relatively strong evidence to separate the northeast and northwest coasts of JDO 1, including fishery CPUE analyses, length and age compositions, and research trawl survey biomass trends. The distribution of John dory on the west coast North Island is continuous between JDO 1 and the northern part of the west coast JDO2, and the combination of these areas is also supported by CPUE analyses. There is evidence to separate the northern South Island from stocks to the north including the occurrence of unusually large fish on the northern South Island, and CPUE analyses. John dory appear to reach the southern limit of their range off the north and northwest coasts of the South Island.

4. STOCK ASSESSMENT

The yield estimates are based on commercial landings data only and have not changed since the 1992 Plenary Report.

4.1 Estimates of fishery parameters and abundance

Relative abundance indices have been obtained from trawl surveys of the Bay of Plenty, west coast North Island, and Hauraki Gulf within the JDO 1 Fishstock (Table 4). However, there was a change in the configuration of the trawl gear following the 1988 trawl survey. Modifications to the trawl gear may have resulted in a change in the catchability of John dory part way through the time series. Therefore, surveys conducted between 1982 and 1988 and from 1989 onwards should be considered separately for comparisons of biomass indices to be valid.

CPUE indices were updated in 2012 (Dunn & Jones 2013). Series based on combined binomial models of fishing success and lognormal models of catch size in the mixed species bottom trawl fisheries for each of the three sub-regions were accepted by the Working Group (Figures 7–10 & 13). The analyses for Hauraki Gulf and east Northland, Bay of Plenty, and west coast North Island, were based on estimated catch and reported effort from tow-by-tow records. The analyses for southeast North Island and northern South Island were based on landed catch allocated to trip-stratum and combined data from the main form types.

In 2014, the CPUE indices for the Northern South Island zone (JDO 7, and part of JDO 2) were revised and updated to include data to 2012/13 (Langley 2014). The CPUE index was based on JDO bycatch from the following bottom trawl targets: BAR, FLA, GUR, JDO, JMA, RCO & TAR, in statistical areas: 33-39.

Hauraki Gulf and east Northland (part of JDO 1)

In Hauraki Gulf and east Northland, the standardised CPUE series shows a cyclical pattern with highs in the mid 1990s and 2000s, but a steady decline after 2004–05 (Figure 7). The index is currently at a low point.

Figure 7: CPUE indices of abundance for Hauraki Gulf and east Northland (part of JDO 1): solid points and line, combined model of catch rates in mixed species bottom trawl tows (Dunn & Jones 2013); dotted line, a lognormal model of positive catches in mixed species bottom trawl tows (Kendrick & Bentley 2011). Indices are scaled to have the same geometric mean over the overlapping years. Vertical lines show the 95% credible intervals. Years labeled as year-ending (i.e., 1990 is 1989–90).

Bay of Plenty (part of JDO 1)

The standardised CPUE series suggests a decline to a series low in 2000–01, and then a period of relative stability (Figure 8).

Figure 8: CPUE indices of abundance for the Bay of Plenty (part of JDO 1): solid points and line, combined model of catch rates in mixed species bottom trawl tows (Dunn & Jones 2013); dotted line, a lognormal model of positive catches in mixed species bottom trawl tows (Kendrick & Bentley 2011). Indices are scaled to have the same geometric mean over the overlapping years. Vertical lines show the 95% credible intervals. Years labeled as year-ending (i.e., 1990 is 1989–90).

West Coast North Island (parts of JDO 1 and JDO 2)

The standardised CPUE series suggests that biomass has been relatively stable since the late 1990s (Figure 9).

Figure 9: CPUE indices of abundance for the West Coast North Island (part of JDO 1 and part of JDO 2): solid points and line, combined model of catch rates in mixed species bottom trawl tows (Dunn & Jones 2013); dotted line, a lognormal model of positive catches in mixed species bottom trawl tows for the west coast North Island (JDO 1 only) (Kendrick & Bentley 2011). Indices are scaled to have the same geometric mean over the overlapping years. Vertical lines show 95% credible intervals. Years labeled as year-ending (i.e., 1990 is 1989–90).

Southeast North Island (part of JDO 2)

The standardised CPUE series suggests an increase in abundance from a low in the mid-1990s to a peak in 2000–01, followed by a steady decline to a series low in 2010–11 (Figure 10).

Figure 10: CPUE indices of abundance for the Southeast North Island (part of JDO 2), combined model of catch rates in mixed species bottom trawl tows (Dunn & Jones 2013). Vertical lines show the 95% credible intervals. Years labeled as year-ending (i.e., 1990 is 1989–90).

Northern South Island (JDO 7, and part of JDO 2)

The Southern Inshore Working Group noted that the West Coast South Island trawl survey series appears to be monitoring trends in abundance of the John dory, particularly recruited biomass (defined as fish of at least 25 cm TL) (Figure 11). Length frequency trends for the John dory survey catch from the West Coast South Island and Tasman Bay/Golden Bay are presented in Figure 12. Smaller (20–35cm) fish tend to be caught in the latter survey region. Biomass levels were low before 2003, with recruited biomass increasing two to three fold since then. Pre-recruits first appeared in 2007, and persisted to 2013.

The last three trawl surveys (2009, 2011 and 2013) have estimated the recruited biomass of John Dory in the WCSI area to be at the highest level of the entire time series (Figure 11).

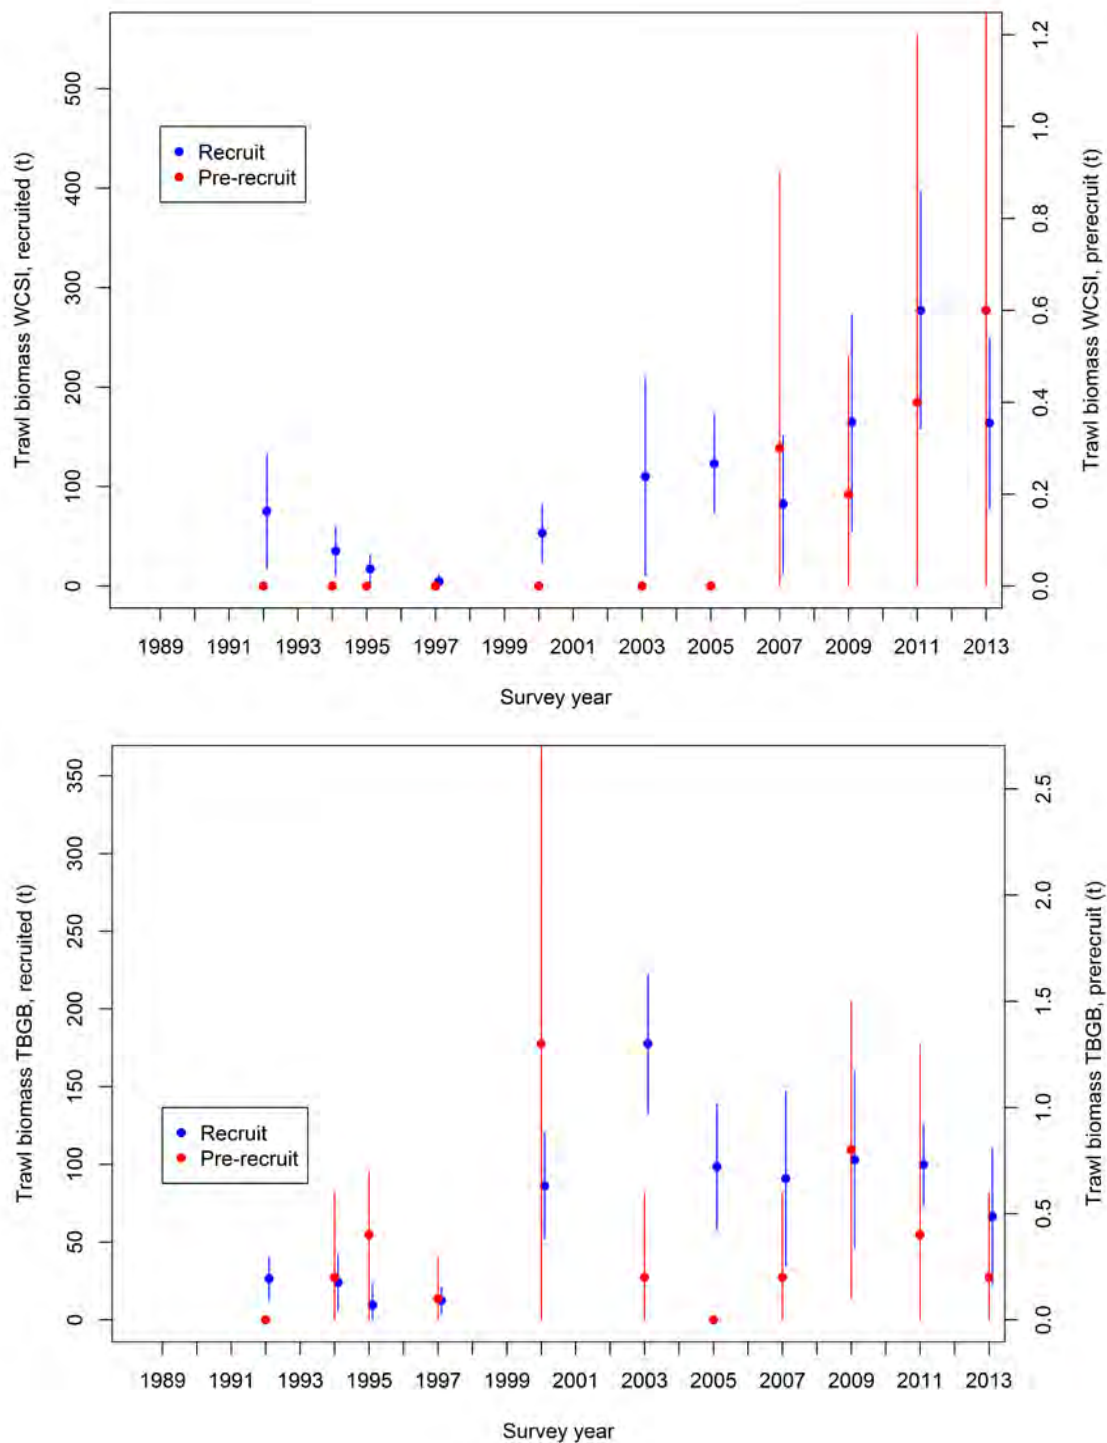

Figure 11: WCSI trawl survey Biomass estimates of recruited and pre-recruit John dory $\pm 95\%$ CI (estimated from survey CVs assuming a lognormal distribution) from the West Coast (top panel) and Tasman Bay/Golden Bays (Bottom Panel).. John dory are assumed to recruit to the commercial fishery at 25 cm TL.

The standardised CPUE series shows a similar trend to the trawl survey biomass index, with a large increase in biomass between the late 1990s and early 2000s, which has persisted to the present (2013) (Figure 13).

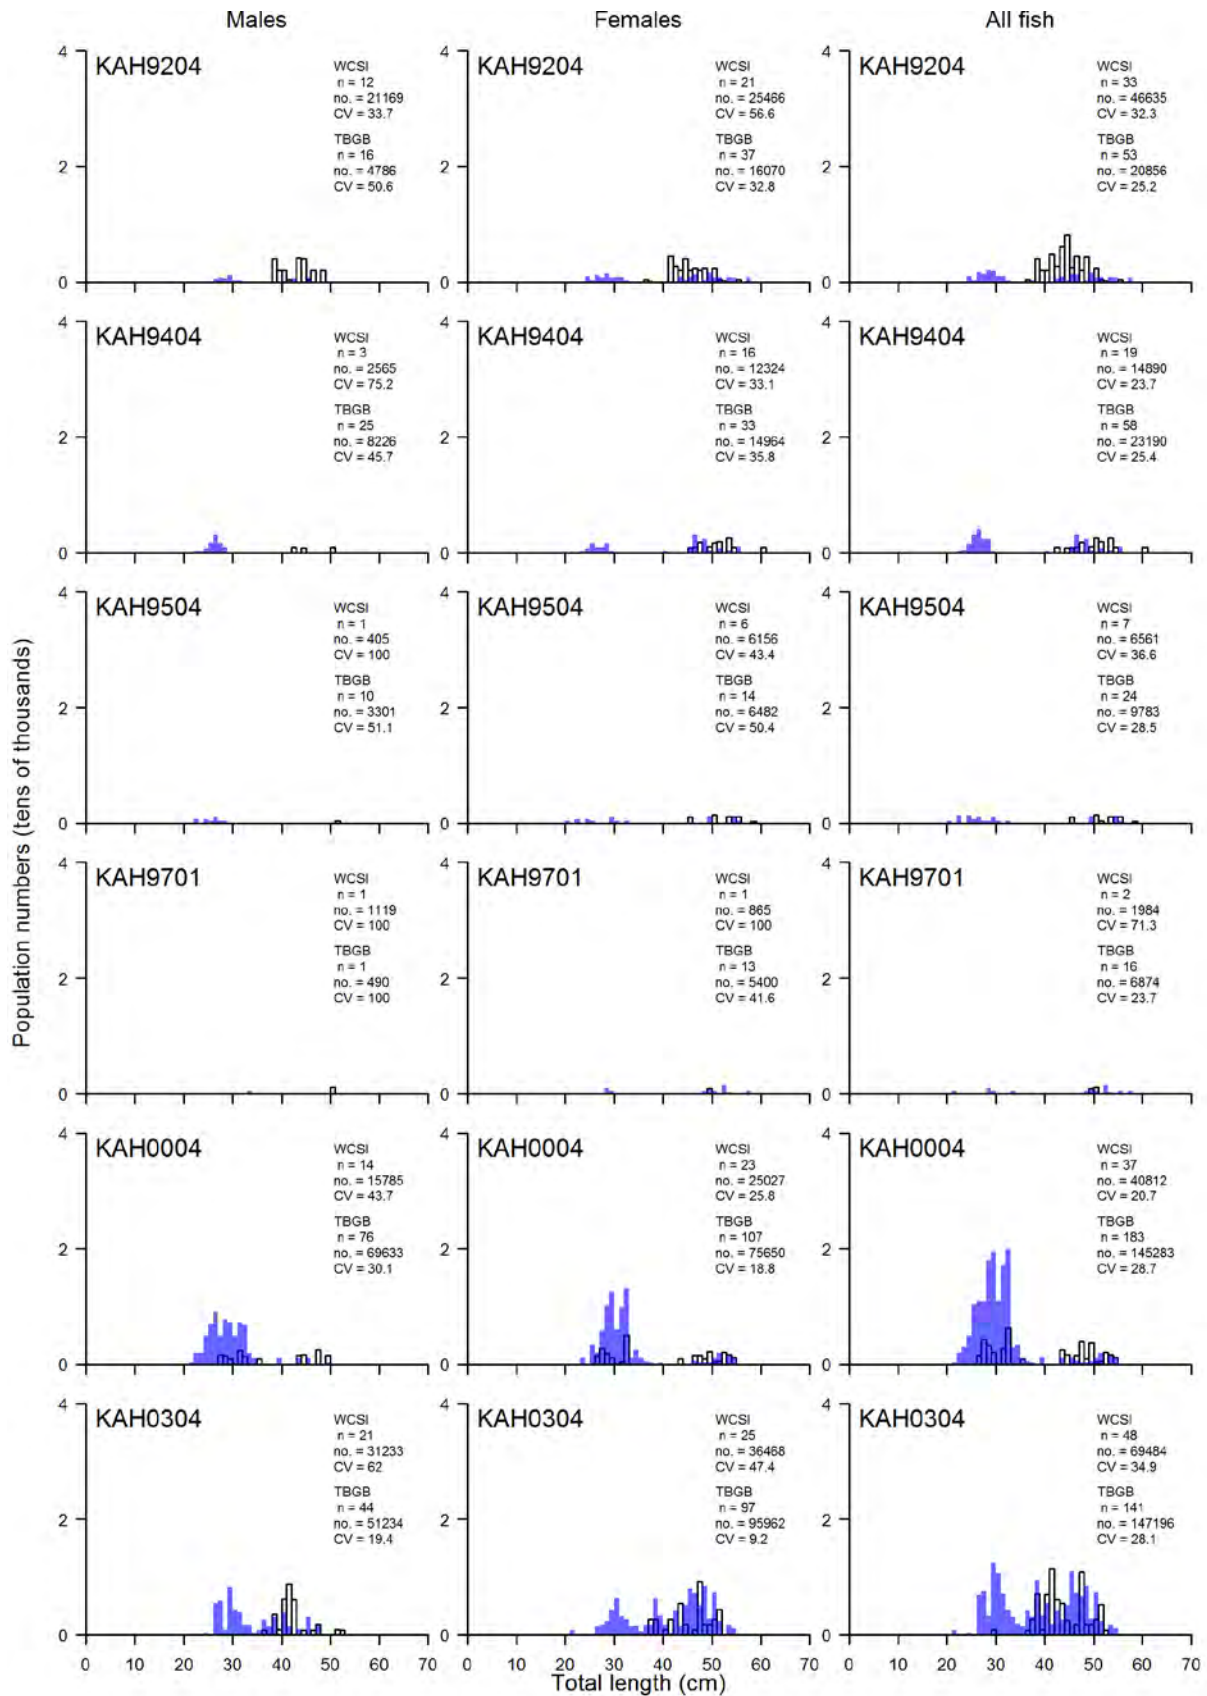

Figure 12: Scaled length frequency distributions for John dory in 30–400 m for West Coast (white) and Tasman Bay/Golden Bay (blue), from WCSI surveys. M, males; F, females; (CV%). [Continued on next page].

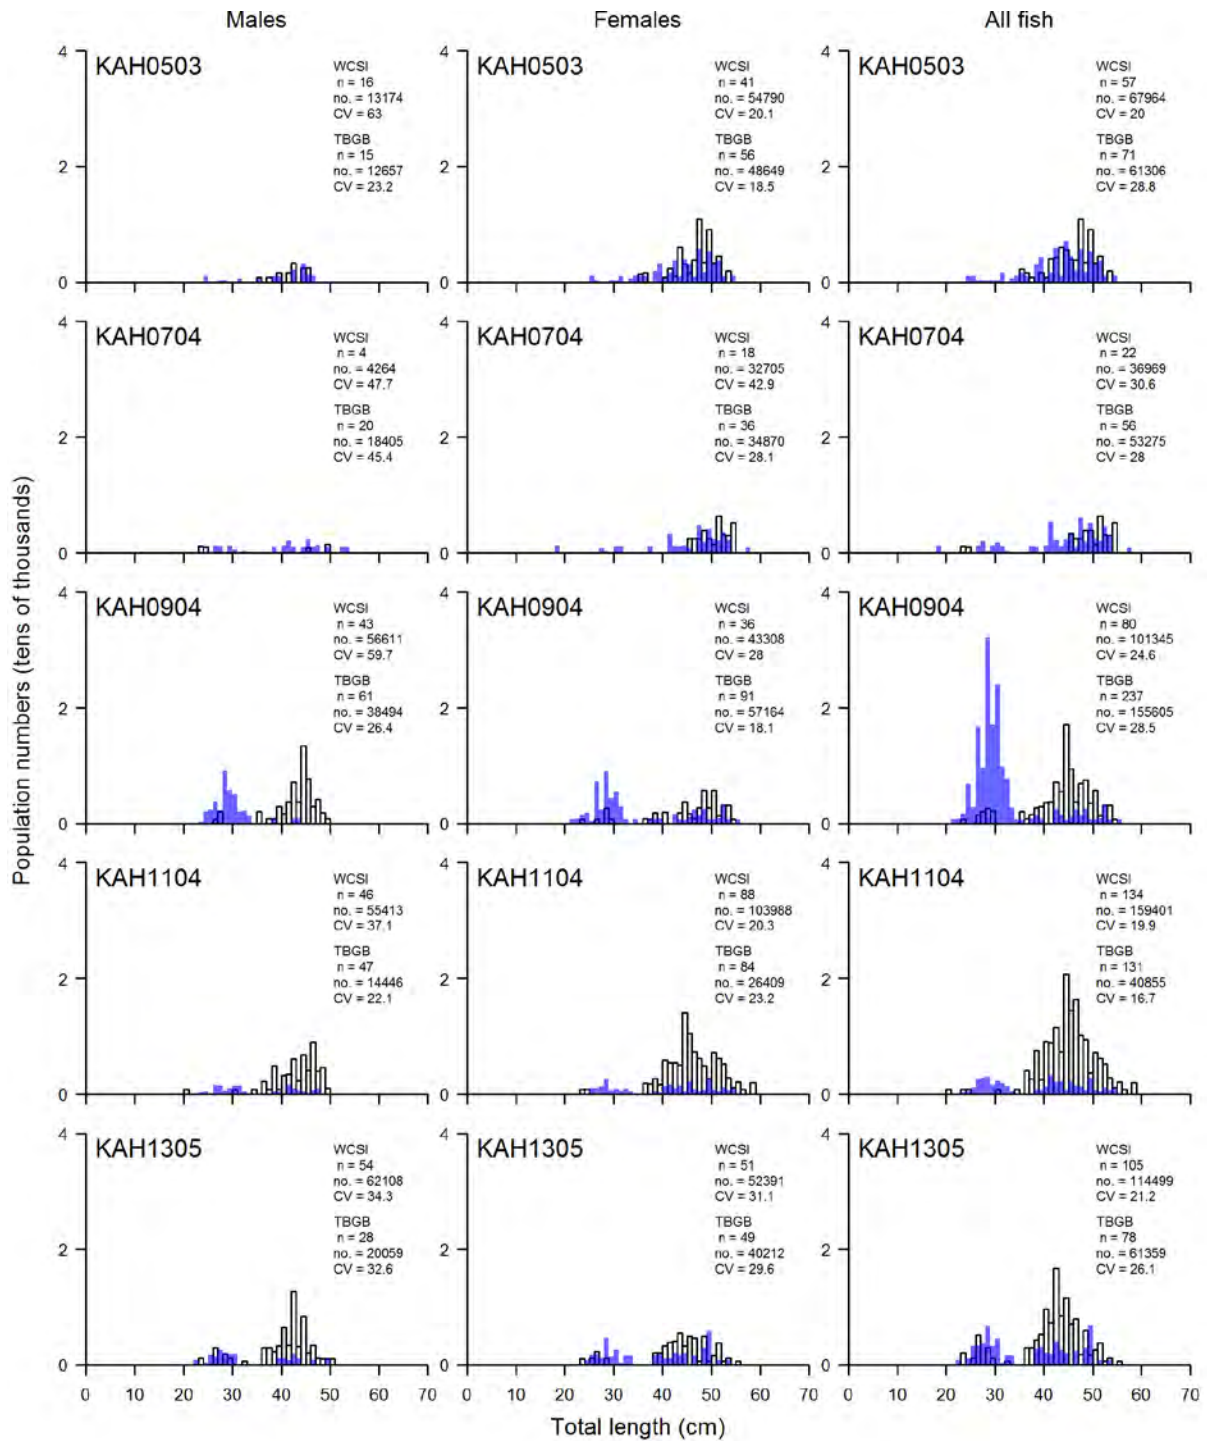

Figure 12 [Continued].

Figure 13: CPUE indices of abundance for the northern South Island (JDO 7 and part of JDO 2), combined model of catch rates in mixed species bottom trawl tows (Langley 2014). Vertical lines show the 95% credible intervals.

4.2 Biomass estimates

Estimates of absolute reference and current biomass are not available.

4.3 Yield estimates and projections

The level of risk to the stock by harvesting the population at the estimated MCY value cannot be determined.

No estimates of current biomass are available which would permit the estimation of *CAY*

4.4 Other yield estimates and stock assessment results

Current estimates of yield are based upon commercial landings only and are assumed to be independent of the non-commercial catch. There was no indication that John dory were overfished at the time of the introduction of the QMS.

5. STATUS OF THE STOCKS

• JDO 1 (Hauraki Gulf and east Northland)

Stock Status	
Year of Most Recent Assessment	2013
Assessment Runs Presented	Standardised CPUE
Reference Points	Interim Target: Mean of the CPUE indices for John dory in Hauraki Gulf and east Northland from combined binomial and lognormal models from 1995–96 to 2010–11 Soft Limit: 50% of target Hard Limit: 25% of target Overfishing threshold: F_{MSY}

Status in relation to Target	Unlikely (< 40%) to be at or above the target	
Status in relation to Limits	Soft Limit: Unlikely (< 40%) to be below Hard Limit: Unlikely (< 40%) to be below	
Status in relation to Overfishing	About as Likely as Not (40–60%) that overfishing is occurring	
Historical Stock Status Trajectory and Current Status		
<p>Standardised CPUE indices for John dory in Hauraki Gulf and east Northland from combined binomial and lognormal models of catch rate in bottom trawl tows in a mixed target fishery (Dunn & Jones 2013). Broken horizontal line indicates the long-term mean from 1995–96 to 2010–11; dotted line, a lognormal model of positive catches in mixed species bottom trawl tows (Kendrick & Bentley 2011). Indices are scaled to have the same geometric mean over the overlapping years. Bars represent catch from this area. Vertical lines show the 95% credible intervals. Years labeled as year-ending (i.e., 1990 is 1989–90).</p>		
Fishery and Stock Trends		
Recent Trend in Biomass or Proxy	The CPUE series has fluctuated but broadly declined. The data points since 2006–07 have been below the long-term mean. 2010–11 is the lowest in the series, and 30% below the long-term mean.	
Recent Trend in Fishing Mortality or Proxy	Unknown	
Other Abundance Indices	-	
Trends in Other Relevant Indicators or Variables	-	
Projections and Prognosis		
Stock Projections or Prognosis	Without information on recruitment, it is not possible to predict how the stock will respond in the next few years.	
Probability of Current Catch or TACC causing decline below Limits	Soft Limit: About as Likely as Not (40–60%) Hard Limit: Unknown	
Probability of Current Catch or TACC causing Overfishing to continue or to commence	-	
Assessment Methodology and Evaluation		
Assessment Type	Level 2 - Partial Quantitative Stock Assessment	
Assessment Method	Standardised CPUE	
Assessment Dates	Latest assessment: 2013	Next assessment: 2016
Overall assessment quality rank	1 – High Quality	
Main data inputs (rank)	- Catch and effort data	1 – High Quality

JOHN DORY (JDO)

Data not used (rank)	N/A
Changes to Model Structure and Assumptions	Use of tow-by-tow catch and effort data.
Major Sources of Uncertainty	Lack of information on incoming recruitment
Qualifying Comments	
As the CPUE trend has declined overall throughout the series it is difficult to establish a B_{MSY} compatible target for this stock. As both catch and CPUE are declining there is some concern over the status of this stock and the analysis should be updated in 2015.	
Fishery Interactions	
John dory is taken on the east coast by bottom trawl and Danish seine targeted at John dory and snapper. Incidental captures of seabirds and dolphins occur; there is a risk of incidental capture of New Zealand fur seal.	

- **JDO 1 (Bay of Plenty)**

Stock Status	
Year of Most Recent Assessment	2013
Assessment Runs Presented	Standardised CPUE
Reference Points	Interim Target: Mean of the CPUE indices for John dory in Bay of Plenty from combined binomial and lognormal models from 1994–95 to 2010–11 Soft Limit: 50% of target Hard Limit: 25% of target Overfishing threshold F_{MSY}
Status in relation to Target	About as Likely as Not (40–60%) to be at or above the target
Status in relation to Limits	Soft Limit: Unlikely (< 40%) to be below Hard Limit: Very Unlikely (< 10%) to be below
Status in relation to Overfishing	Unknown

Historical Stock Status Trajectory and Current Status

Standardised CPUE indices for John dory in Bay of Plenty from combined binomial and lognormal models of catch rate in bottom trawl tows in a mixed target fishery (Dunn & Jones 2013). Broken horizontal line indicates the mean from 1994–95 to 2010–11; dotted line, a lognormal model of positive catches in mixed species bottom trawl tows (Kendrick & Bentley 2011). Indices are scaled to have the same geometric mean over the overlapping years. Bars represent catch from this area. Vertical lines show the 95% credible intervals. Years labeled as year-ending (i.e., 1990 is 1989–90).

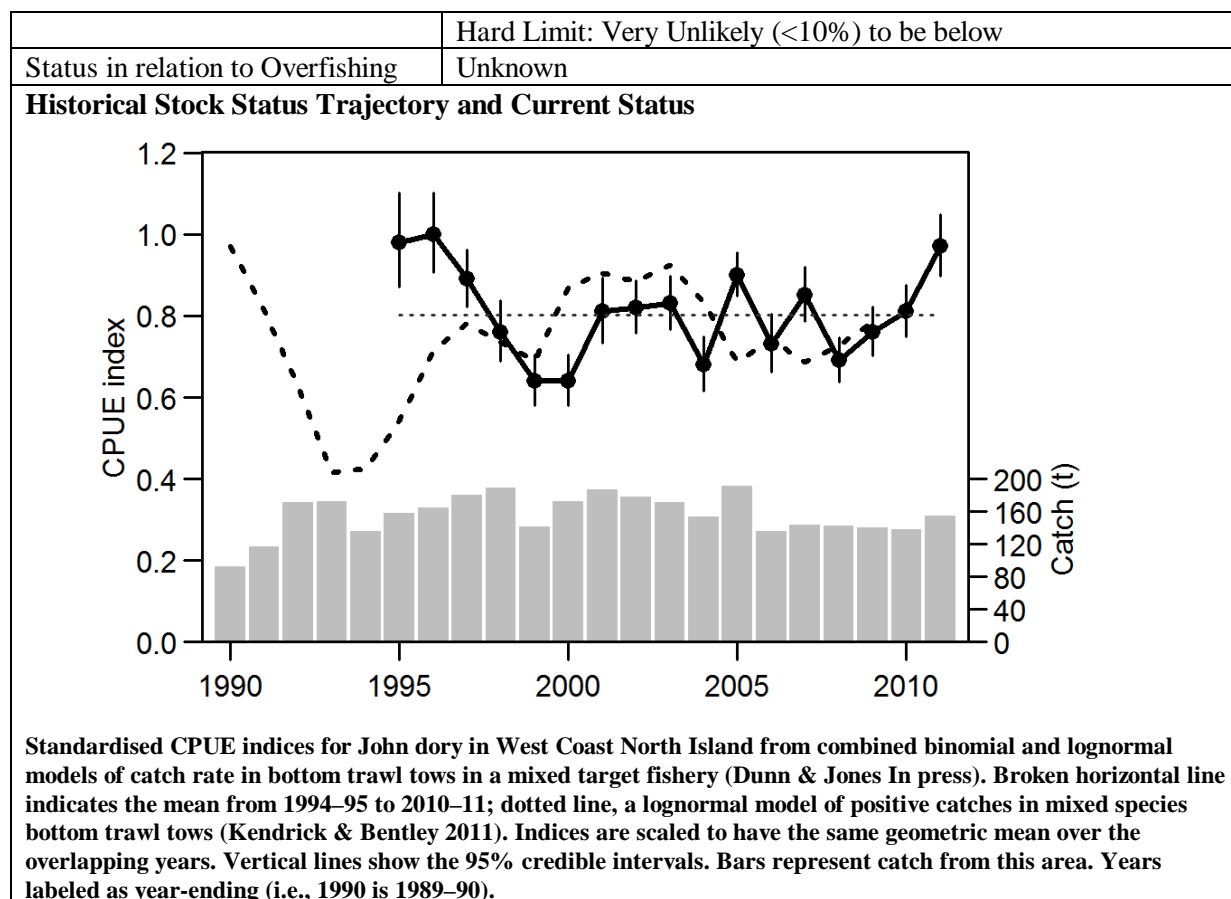

Fishery and Stock Trends	
Recent Trend in Biomass or Proxy	The CPUE series declined in the late 1990s. Since the early 2000s the series has fluctuated without trend close to the long-term mean.
Recent Trend in Fishing Mortality or Proxy	Unknown
Other Abundance Indices	-
Trends in Other Relevant Indicators or Variables	-

Projections and Prognosis	
Stock Projections or Prognosis	Without information on recruitment, it is not possible to predict how the stock will respond in the next few years.
Probability of Current Catch or TACC causing decline below Limits	Soft Limit: Unknown Hard Limit: Unknown
Probability of Current Catch or TACC causing Overfishing to continue or to commence	-
Assessment Methodology and Evaluation	
Assessment Type	Level 2 - Partial Quantitative stock assessment
Assessment Method	Fishery characterisation and standardised CPUE
Assessment Dates	Latest assessment: 2013 Next assessment: 2016
Overall assessment quality rank	1 – High Quality
Main data inputs (rank)	2013 CPUE analysis 1 – High Quality 2010 CPUE analysis 1 – High Quality
Data not used (rank)	-
Changes to Model Structure and Assumptions	Use of tow-by-tow catch and effort data
Qualifying Comments	
As the John dory fishery in FMAs 1 and 9 has a long history, it is not possible to infer stock status from abundance trends from only the last 22 years. This sub-stock appears to be cyclical, probably in response to recruitment variation, and the current trend is downward. This makes it difficult to predict future trends without recruitment information.	

Fishery Interactions
John dory is taken in the Bay of Plenty by bottom trawl targeted at John dory, snapper, trevally, tarakihi and gurnard; and by Danish seine targeted at snapper and gurnard. Incidental captures of seabirds and dolphins occur; there is a risk of incidental capture of New Zealand fur seal.

- **JDO 1 (West Coast North Island)**

Stock Status	
Year of Most Recent Assessment	2012
Assessment Runs Presented	Standardised CPUE
Reference Points	Interim Target: Mean of the CPUE indices for John dory in West Coast North Island from combined binomial and lognormal models from 1994–95 to 2010–11 Soft Limit: 50% of target Hard Limit: 25% of target Overfishing threshold F_{MSY}
Status in relation to Target	About as Likely as Not (40–60%) at or above the target
Status in relation to Limits	Soft Limit: Unlikely (< 40%) to be below

Fishery and Stock Trends	
Recent Trend in Biomass or Proxy	Both CPUE series have fluctuated without trend.
Recent Trend in Fishing Mortality or Proxy	Unknown
Other Abundance Indices	-
Trends in Other Relevant Indicators or Variables	-
Projections and Prognosis	
Stock Projections or Prognosis	Without information on recruitment, it is not possible to predict how the stock will respond in the next few years.
Probability of Current Catch or TACC causing decline below Limits	Soft Limit: Unknown Hard Limit: Unknown
Probability of Current Catch or TACC causing Overfishing to continue or to commence	-

Assessment Methodology		
Assessment Type	Level 2 - Partial Quantitative Stock Assessment	
Assessment Method	Fishery characterisation and standardised CPUE	
Assessment Dates	Latest assessment: 2013	Next assessment: 2016
Overall assessment quality rank	1 – High Quality	
Main data inputs (rank)	2013 CPUE analysis 2010 CPUE analysis	1 – High Quality 1 – High Quality
Data not used (rank)	N/A	
Changes to Model Structure and Assumptions	The West Coast North Island stock now includes the northern part of JDO 2 west coast and the analysis is based on tow-by-tow	

	catch and effort data.
Major Sources of Uncertainty	- The stock relationship between JDO 1 and JDO 2 - Lack of information on incoming recruitment.

Qualifying Comments

-

Fishery Interactions

John dory is taken on the west coast by bottom trawl targeted at snapper trevally, gurnard and tarakihi. Incidental captures of seabirds and dolphins occur; there is a risk of incidental capture of New Zealand fur seal and Maui's dolphins.

- **JDO 2 (Southeast North Island)**

Stock Status

Year of Most Recent Assessment	2013
Assessment Runs Presented	Standardised CPUE
Reference Points	Interim Target: Mean of the CPUE indices for John dory in South East coast of the North Island from combined binomial and lognormal models from 1989–90 to 2010–11 Soft Limit: 50% of target Hard Limit: 25% of target Overfishing threshold F_{MSY}
Status in relation to Target	Unlikely (< 40%) to be at or above the target
Status in relation to Limits	Soft Limit: About as Likely as Not (40–60%) to be below Hard Limit: Unlikely (< 10%) to be below
Status in relation to Overfishing	Unknown

Historical Stock Status Trajectory and Current Status

Standardised CPUE indices for John dory in Southeast North Island from combined binomial and lognormal models of catch rate in bottom trawl trips in a mixed target fishery (Dunn & Jones In press). Broken horizontal line indicates the mean from 1989–90 to 2010–11; Bars represent catch from this area.

Fishery and Stock Trends

Recent Trend in Biomass or Proxy	The CPUE series has fluctuated with a cyclical trend. The data points since 2006–07 have been below the long-term mean. 2010–11 is the lowest in the series.

Major Sources of Uncertainty	- The stock relationship between JDO 1 and JDO 2 - Lack of information on incoming recruitment

Qualifying Comments
As the John dory fishery in FMAs 1 and 9 has a long history, it is not possible to infer stock status from abundance trends from only the last 22 years. This sub-stock appears to be cyclical, probably in response to recruitment variation. This makes it difficult to predict future trends without recruitment information.

Fishery Interactions
John dory is taken on the east coast by bottom trawl targeted primarily at tarakihi and red gurnard.

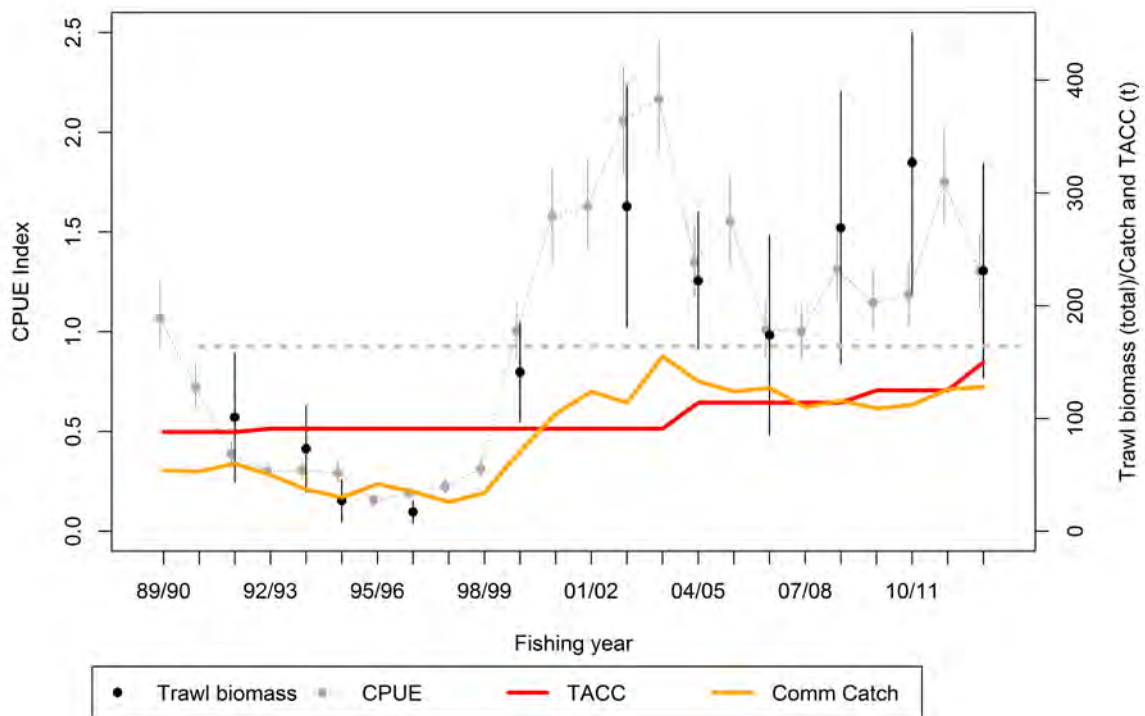

• **JDO 7 (Northern South island)**

Stock Status	
Year of Most Recent Assessment	2014
Assessment Runs Presented	Trawl survey biomass index and standardised CPUE
Reference Points	Interim Target: Mean total biomass from the West Coast South Island trawl survey (WCSI and TBGB) from 1992 to 2011 Soft Limit: 50% of target Hard Limit: 25% of target Overfishing threshold F_{MSY}
Status in relation to Target	Likely (> 60%) to be above the target
Status in relation to Limits	Soft Limit: Very Unlikely (< 10%) to be below Hard Limit: Very Unlikely (< 10%) to be below
Status in relation to Overfishing	Overfishing is Unlikely (< 40%) to be occurring

Historical Stock Status Trajectory and Current Status

Biomass trends $\pm 95\%$ CI (estimated from survey CVs assuming a lognormal distribution) and the time series mean (dotted line) from the Challenger trawl surveys.

A comparison of trends in trawl survey biomass estimates (total biomass, WCSI), CPUE indices and the commercial catch relative to the TACC. The dashed line represents the interim target biomass level relative to the trawl survey biomass indices.

Fishery and Stock Trends

Recent Trend in Biomass or Proxy

The trawl survey series declined through the 1990s then increased between 1997–98 and 2003–04. The series has been above the long term mean since 2000–01. Trends in CPUE are comparable to trawl survey biomass trends.

JOHN DORY (JDO)

Recent Trend in Fishing Mortality or Proxy	The commercial catch trends generally followed those of the trawl survey biomass estimates up to 2006/07. Since then, the annual catch has been maintained at about the annual TACC level, while trawl survey biomass has increased.
Other Abundance Indices	–
Trends in Other Relevant Indicators or Variables	Length frequency analysis from the West Coast South Island trawl survey showed very good recruitment in 2000, 2003 and 2009 and these are probably supporting the high biomass at this time. Recruitment from the 2011 and 2013 surveys is more modest.

Projections and Prognosis		
Stock Projections or Prognosis	The stock is currently at a relatively high level, above the interim target biomass level, and previous high catches appear to have been sustained by intermittent high recruitment. Biomass levels may decline below the target biomass level if strong recruitment does not occur in the next few years.	
Probability of Current Catch / TACC causing decline below Limits	Soft Limit: Unlikely (< 40%) Hard Limit: Unlikely (< 40%)	
Probability of Current Catch or TACC causing Overfishing to continue or to commence	Unlikely (< 40%). Non target species so that even if abundance declines considerably the exploitation rates are unlikely to substantially increase.	
Assessment Methodology and Evaluation		
Assessment Type	Level 2 - Partial Quantitative Stock Assessment	
Assessment Method	Evaluation of survey biomass and length frequencies. Standardised CPUE	
Assessment Dates	Latest assessment: 2013 (Survey) 2014 (CPUE)	Next assessment: 2015 (survey) 2016 (CPUE)
Overall assessment quality rank	1 – High Quality	
Main data inputs (rank)	- West Coast South Island trawl survey - Survey length frequency - CPUE	1 – High Quality 1 – High Quality 1 – High Quality
Data not used (rank)	N/A	
Changes to Model Structure and Assumptions	More complete data set obtained for CPUE analysis	
Major Sources of Uncertainty	- The stock relationship between JDO 7 and JDO 2	

Qualifying Comments
-
Fishery Interactions
John dory are primarily taken in conjunction with the following QMS species: barracouta, red cod, stargazer, red gurnard and tarakihi in the Northern South Island bottom trawl fishery. (AEWG)

KAHAWAI (KAH)

(*Arripis trutta* and *Arripis xylabion*)
Kahawai

1. FISHERY SUMMARY

Kahawai (*Arripis trutta*) and Kermadec kahawai (*Arripis xylabion*) were introduced into the QMS on 1 October 2004 under a single species code, KAH. Within the QMS, kahawai management is based on six QMAs (KAH 1, KAH 2, KAH 3, KAH 4, KAH 8 and KAH 10).

These QMAs differ from the Management Areas used before kahawai were introduced into the QMS. The definitions of KAH 1, KAH 2 and KAH 10 remain unchanged, but KAH 4 was formerly part of KAH 3, as was that part of KAH 8 which is south of Tirua Point. The area of KAH 8 which is north of Tirua point was formerly called KAH 9.

TACs totalling 7612 t were set on introduction into the QMS. These TACs were based on a 15% reduction from both the level of commercial catch and assumed recreational use prior to introducing kahawai into the QMS. The Minister reviewed the TACs for kahawai for the 2005–06 fishing year. Subsequently, he decided to reduce TACs, TACCs and allowances by a further 10% as shown in Table 1.

Table 1: KAH allowances, TACCs, and TACs, 1 October 2005.

Fishstock	Recreational Allowance	Customary Non-Commercial Allowance	Other mortality	TACC	TAC
KAH 1	1680	495	65	1 075	3 315
KAH 2	610	185	30	705	1 530
KAH 3	390	115	20	410	935
KAH 4	4	1	0	9	14
KAH 8	385	115	20	520	1 040
KAH 10	4	1	0	9	14

1.1 Commercial fisheries

Commercial fishers take kahawai by a variety of methods. Purse seine vessels take most of the catch; however, substantial quantities are also taken seasonally in set net fisheries and as a bycatch in longline and trawl fisheries.

The kahawai purse seine fishery cannot be understood without taking into account the other species that the vessels target. The fleet, which is based in Tauranga, preferentially targets skipjack tuna

(*Katsuwonus pelamis*) between December and May, with very little bycatch. When skipjack are not available, usually from June through to November, the fleet fishes for a mix of species including kahawai, jack mackerels (*Trachurus* spp.), trevally (*Pseudocaranx dentex*) and blue mackerel (*Scomber australasicus*). These are caught 'on demand' as export orders are received (to reduce product storage costs). However, since the mackerels and kahawai school together there is often a bycatch of kahawai resulting from targeting of mackerels. Reported landings, predominantly of *A. trutta*, are shown for 1962 up to and including 1982 in Table 2 by calendar year for all areas combined, and from 1983–84 onwards by fishing year and by historic management areas in Table 3 and by QMAs in Table 4. The historical landings and TACC for the main KAH stocks are depicted in Figure 1.

Table 2: Reported total landings (t) of kahawai from 1970 to 1982. Note that these data include estimates of kahawai from data where kahawai were reported within a general category of 'mixed fish' rather than separately as kahawai.

Year	Landings	Year	Landings	Year	Landings
1962	76	1969	234	1976	729
1963	81	1970	294	1977	1 461
1964	86	1971	572	1978	2 228
1965	102	1972	394	1979	3 782
1966	254	1973	586	1980	5 101
1967	457	1974	812	1981	3 794
1968	305	1975	345	1982	5 398

Source: 1962 to 1969 - Watkinson & Smith (1972); 1970 to 1982 - Sylvester (1989).

Before 1988 there were no restrictions in place for the purse seine fishery.

Table 3: Reported landings (t) of kahawai by management areas as defined prior to 2004 from 1983–84 to 2003–04. Estimates of fish landed as bait or as 'mixed fish' are not included. Data for the distribution of catches among management areas and total catch are from the FSU database through to 1987–88 and from the CELR database after that date. Total LFRR or MHR values are the landings reported by Licensed Fish Receivers (to 2000–01) or on Monthly Harvest returns (to 2003–04).

Fishstock	KAH 1	KAH 2	KAH 3	KAH 9	KAH 10	Unknown Area	Total Catch	Total LFRR/MHR

2003–04	1 624	807	109	205	0	0	2 745	2 754

A total commercial catch limit for kahawai was set at 6500 t for the 1990–91 fishing year, with 4856 t set aside for those harvesting kahawai by purse seine (Table 5). Before the 2002–03 fishing year a high proportion of the purse seine catch was targeted, but in recent years approximately half of the landed catch has been reported as a bycatch whilst targeting other species with purse seine gear.

KAHAWAI (KAH)

Table 4: Prorated landings (t) of kahawai by the Fishstocks defined in 2004 for the fishing years between 1998–99 and 2012–13. Distribution of data were derived by linking through the trip code, catch landing data (CLD), statistical areas and landing points and prorating to CLD totals. Landings since 2004–05 are from QMS MHR data. The TACC is provided for those years since the introduction to the QMS.

In KAH 1, a voluntary moratorium was placed on targeting kahawai by purse seine in the Bay of Plenty from 1 December 1990 to 31 March 1991, which was extended from 1 December to the Tuesday after Easter in subsequent years. While total landings decreased in 1991–92, landings in KAH 1 increased, and in 1993–94 the competitive catch limit for purse seining in KAH 1 was reduced from 1666 t to 1200 t. Purse seine catches reported for KAH 9 were also included in this reduced catch limit, although seining for kahawai on the west coast of the North Island ceased after the reduction in the KAH 1 purse seine limit. Purse seine catch limits were reached in KAH 1 between 1998–99 and 2000–01 and in 2003–04.

Prior to the introduction to the QMS, no change was made to the purse seine limit of 851 t for KAH 2. The KAH 2 purse seine fishery was closed early due to the catch limit being reached before the end of the season in each year between 1991–92 and 1995–96 and between 2000–01 and 2001–02.

Within KAH 3, the kahawai purse seine fleet has voluntarily agreed since 1991–92 not to fish in a number of near-shore areas around Tasman and Golden Bays, the Marlborough Sounds, Cloudy Bay, and Kaikoura. The main purpose of this agreement is to minimise local depletion of schools of kahawai found inshore, and the catches of juveniles. The purse seine catch limit for KAH 3 was reduced from 2339 to 1500 tonnes from 1995–96. Purse seine catch limits have never been reached in KAH 3.

Table 5: Reported catches (t) by purse seine method and competitive purse seine catch limit (t) from 1990–91 to 2003–04. All data are from weekly reports furnished by permit holders to the Ministry of Fisheries except those for 1993–94 which are from the CELR database. Fishstocks are as defined prior to 2004.

By March 1991 when the catch limit was imposed, the purse seine catch had already exceeded 2339 t and the fishery was immediately closed. As the catch already exceeded 2339 t before the Minister's decision was announced, an extra 500 t was allocated to cover kahawai bycatch only.

§ Combined landings from KAH 9 and KAH 1 were limited to 1200 t.

* Purse seine fishery for kahawai closed.

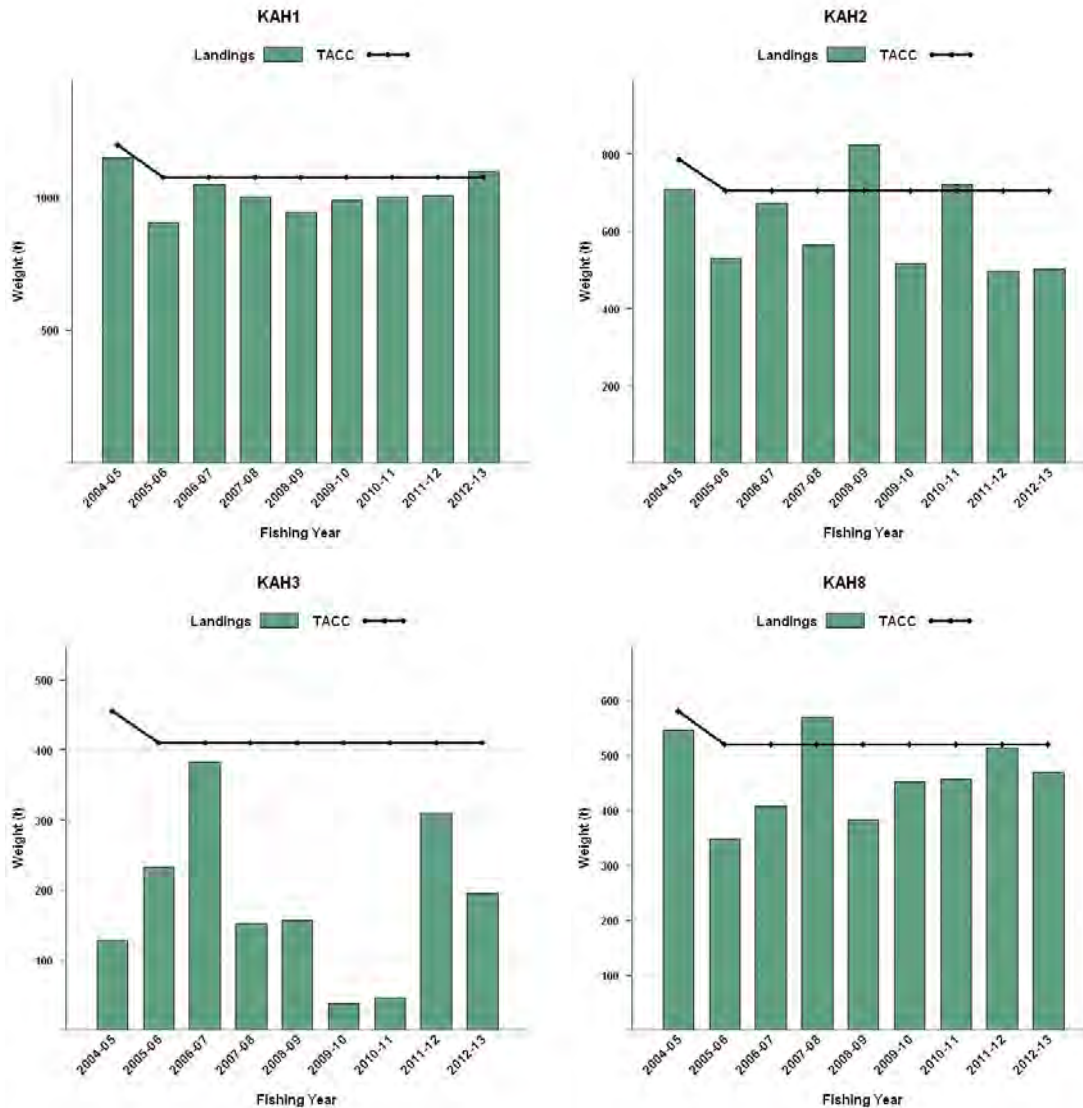

Figure 1: Historical landings and TACC for the four main KAH stocks. From top left to bottom right: KAH 1 (Auckland East), KAH 2 (Central East), KAH 3 (South East Coast, South East Chatham Rise, Sub-Antarctic, Southland, Challenger), and KAH 8 (Central Egmont, Auckland West).

Since kahawai entered the Quota Management System on 1 October 2004, the purse seine catch limits no longer apply and landings, regardless of fishing method, are now restricted by quota availability and fishing company policies.

1.2 Recreational fisheries

Kahawai is the second most important recreational species in FMA 1 (after snapper). Kahawai are highly prized by some recreational fishers, who employ a range of shore and boat based fishing methods to target and/or catch the species. Kahawai is one of the fish species more frequently caught by recreational fishers, and recreational groups continue to express concern about the state of kahawai stocks. Historical kahawai recreational catches are poorly known. The current allowances within the TAC for each Fishstock are shown in Table 1.

1.2.1 Management controls

The main method used to manage recreational harvests of kahawai is the daily bag limits. The current limit for kahawai is a multi-species bag limit of 20 fish and a minimum set net mesh size of 90 mm.

1.2.1 Harvest estimates

The first recreational harvest estimates were obtained from regional telephone diary surveys undertaken in 1991–92 in the South Region, 1992–93 in the Central Region and in 1993–94 in the

KAHAWAI (KAH)

North Region. National telephone diary surveys were undertaken in 1996 and 2000, with a follow up survey in 2001 (i.e., the 2000 and 2001 estimates are not independent). Combined aerial overflight/boat ramp surveys, focusing on snapper, have provided kahawai harvest estimates in 2004 (Hauraki Gulf only) and 2005 (FMA 1 only).

Detailed descriptions for the telephone diary approaches used can be found in Teirney et al (1997), Bradford et al (1998) and Reilly (2002). The aerial overflight methodology is described in Hartill et al (2007b & c). The key difference between the two approaches is that the telephone diary methodology combines unobserved estimates of the number of fishers in an area obtained via a survey of randomly selected individuals from telephone listings, with volunteer diarist data (which is used to estimate the average catch per fisher), whereas the aerial overflight approach combines aerial counts of boats fishing at mid day with dawn to dusk boat ramp interviews describing fishing effort and catch. The aerial overflight survey is, therefore, based on a direct assessment of the fishery while the telephone diary method is indirect, particularly with respect to the estimate of active participants. It is not, however, possible to reliably quantify shore based fishing from the air, and for this reason it was necessary to derive scalars from 2001 diarist data to account for the shore based kahawai catch (28% of the 2001 estimate).

Recreational harvest estimates are given in Tables 6 (telephone diary surveys) and 7 (Aerial overflight surveys).

Table 6: Estimated kahawai harvest by recreational fishers (in numbers and weight) by Fishstock as defined prior to 2004. (Source: Tierney et al 1997, Bradford 1997, Bradford 1998, Boyd & Reilly 2002, Boyd et al 2004).

#No harvest estimate available in the survey report, estimate presented is calculated as average fish weight for all years and areas by the number of fish estimated caught.

Table 7: Summary of kahawai harvest estimates (t) derived from an aerial overflight survey of the Hauraki Gulf in 2003–04 (1 December 2003 to 30 November 2004; Hartill et al 2007b) and a similar KAH 1 wide survey conducted in 2004–05 (1 December 2004 to 30 November 2005; Hartill et al 2007c). Values in brackets denote CVs associated with each estimate.

Year	East Northland	Hauraki Gulf	Bay of Plenty	KAH 1
2003–04	-	56 (0.15)	-	-
2004–05	129 (0.14)	98 (0.18)	303 (0.14)	530 (0.09)

The Recreational Technical Working Group (RTWG) concluded that the framework used for the telephone interviews for the 1996 and previous surveys contained a methodological error, resulting in biased eligibility figures. Consequently the harvest estimates derived from these surveys are unreliable.

This group also indicated concerns with some of the harvest estimates from the 2000–01 survey. The following summarises that group's views on the telephone /diary estimates:

“The RTWG recommends that the harvest estimates from the diary surveys should be used only with the following qualifications: a) they may be very inaccurate; b) the 1996 and earlier surveys contain

a methodological error; and, c) the 2000 and 2001 harvest estimates are implausibly high for many important fisheries.”

In 2007, the Pelagic Working Group made the following conclusions in relation to the recreational harvest estimates for KAH 1 based on their current understanding:

- recreational catches are likely to be variable between years;
- the 2000 and 2001 harvest estimates (2195 and 2248 t) are:
 - possibly overestimated for those years and some PELWG members felt that the estimates were implausibly high;
 - are implausibly high if considered as a long term (back to the early 1990s) average; and
 - are likely to represent the upper limit of the harvest that may have occurred in any year since the 1990s (after the period of increased commercial landings);
- the aerial overflight estimate for kahawai harvest in 2004–05 of 530 t is:
 - possibly underestimated for that year, and
 - some PELWG members felt that it was implausibly low if considered as a long term average back to the early 1990s;
- the earlier diary survey estimates, although biased, are likely to be at plausible levels for those years, but are still uncertain; and
- the aerial overflight estimates for kahawai should be treated with caution due to the limited overlap between the method’s sampling technique and the fisheries for kahawai, e.g., the significant proportion of harvest taken by shore-based methods that requires auxiliary data to allow estimation of total harvest.

In 2008, the Northern Inshore Finfish Working Group (NINSWG) made the following conclusions in relation to the recreational harvest estimates for other KAH QMAs based on their conclusions for KAH 1:

- the current KAH QMAs do not match up with the strata used for the historical harvest estimates (KAH 3 and 8);
- recreational catches are likely to be variable between years;
- the 2000 harvest estimate for KAH 2 is implausibly high;
- the 2000 and 2001 harvest estimates for the remaining KAH areas are possibly overestimated.

In response to the cost and scale challenges associated with onsite methods, in particular the difficulties in sampling other than trailer boat fisheries, offsite approaches to estimating recreational fisheries harvest have been revisited. This led to the development and implementation of a national panel survey for the 2011–12 fishing year. The panel survey used face-to-face interviews of a random sample of New Zealand households to recruit a panel of fishers and non-fishers for a full year. The panel members were contacted regularly about their fishing activities and catch information collected in standardised phone interviews. Note that the national panel survey estimate does not include harvest taken on recreational charter vessels, or recreational harvest taken under s111 general approvals. Recreational harvest estimates from this survey for kahawai were: 933 t (cv 0.07) in KAH 1; 227 t (cv 0.12) in KAH 2; 146 t (cv 0.18) in KAH 3; and 415 t (cv 0.12) in KAH 8.

The most recent aerial-access survey was conducted in QMA 1 in 2011–12 (Hartill et al 2013), to independently provide harvest estimates for comparison with those generated from the concurrent national panel survey. The KAH 1 recreational harvest estimate from this survey was 942 t (cv 0.08).

Both surveys appear to provide plausible results that corroborate each other for KAH 1, and are therefore considered to be broadly reliable (Hartill et al 2013). Note that neither of these estimates includes catch taken on recreational charter vessels, or recreational catch taken under s111 general approvals.

1.3 Customary non-commercial fisheries

Kahawai is an important traditional and customary food fish for Maori. The level of customary catch has not been quantified and an estimate of the current customary non-commercial catch is not

KAHAWAI (KAH)

available. Some Maori have expressed concern over the state of their traditional fisheries for kahawai, especially around the river mouths in the eastern Bay of Plenty.

1.4 Illegal catch

Estimates of illegal catch are not available, but are probably insignificant.

1.5 Other sources of mortality

There is no information on other sources of mortality. Juvenile kahawai may suffer from habitat degradation in estuarine areas.

2. BIOLOGY

Kahawai (*Arripis trutta*) are a schooling pelagic species belonging to the family Arripidae. Kahawai are found around the North Island, the South Island, the Kermadec and Chatham Islands. They occur mainly in coastal seas, harbours and estuaries and will enter the brackish water sections of rivers. A second species, *A. xylabion*, has been described (Paulin 1993). It is known to occur in the northern EEZ, at the Kermadec Islands and seasonally around Northland.

Kahawai feed mainly on fishes but also on pelagic crustaceans, especially krill (*Nyctiphanes australis*). Kahawai smaller than 100 mm mainly eat copepods. Although kahawai are principally pelagic feeders, they will take food from the seabed.

The spawning habitat of kahawai is unknown but is thought to be associated with the seabed in open water. Schools of females with running ripe ovaries have been caught by bottom trawl in 60–100 m in Hawke Bay (Jones et al 1992). Other females with running ripe ovaries have been observed in east coast purse seine landings sampled in March and April 1992, and between January and April in 1993 (McKenzie NIWA, unpublished data). Length-maturation data collected from thousands of samples in the early 1990s suggest that the onset of sexual maturity in males occurs at around 39 cm and in females at 40 cm (McKenzie NIWA, unpublished data). This closely matches an estimate of 39 cm used for Australian *A. trutta* (Morton et al 2005). This length roughly corresponds to fish of four years of age in both countries. Eggs have been found in February in the outer Hauraki Gulf. Juvenile fish (0+ year class) can be found in shallow water over eelgrass meadows (*Zostera* spp.) and in estuaries.

Kahawai are usually aged using otoliths, following an ageing technique that has been validated (Stevens & Kalish 1998). Kahawai grow rapidly, attaining a length of around 15 cm at the end of their first year, and maturing after 3–5 years at about 35–40 cm, after which their growth rate slows. The longest recorded *A. trutta* had a fork length of 79 cm and was caught by a recreational fisher in the Waitangi Estuary, in Hawke Bay in August 1997 (Duffy & Petherick 1999). Northern kahawai, *Arripis xylabion*, grow considerably bigger than kahawai and attain a maximum length of at least 94 cm, but beyond this, little is known about the biology of *A. xylabion*. Male and female von Bertalanffy growth curves appear to be broadly similar, with females attaining a slightly higher value for L_{∞} , although statistical comparison of sex specific curves using a likelihood ratio test (Kimura 1980) suggests that they are statistically different (Hartill & Walsh 2005). Combined-sex growth curves are probably adequate for modelling purposes and are provided for some areas in Table 8. Sex specific growth parameters given for KAH 1 in previous plenary documents have higher estimates for L_{∞} (56.93 for males and 55.61 for females).

The maximum recorded age of kahawai is 26 years. The instantaneous rate of natural mortality (M) was estimated from the equation $M = \log_e 100/\text{maximum age}$, where maximum age is the age to which 1% of the population survives in an unexploited stock. Based on a maximum age of 26 years, M was estimated to equal 0.18. A range of 0.15–0.25 has previously been assumed to reflect the lack of precision in the estimate.

Table 8: Estimates of biological parameters.

Fishstock	Estimate			Source

KAH 3	0.3	0.25	54.2	Drummond & Wilson (1993)
KAH 9	0.23	-0.26	55.9	McKenzie, NIWA, unpubl. data

3. STOCKS AND AREAS

Kahawai are presently defined as separate units for the purpose of fisheries management: KAH 1 (FMA 1); KAH 2 (FMA 2); KAH 3 (FMAs 3, 5, 6 & 7); KAH 4 (QMA 4); KAH 8 (FMAs 8 & 9) and KAH 10 (FMA 10).

Returns from tagging programmes do not provide definitive information on the level of potential mixing between KAH QMAs, but tagging returns suggest that most kahawai (*A. trutta*) remain in the same area for several years, but some move throughout the kahawai habitat. The pattern of kahawai movement around New Zealand is poorly understood and there are regional differences in age structure and abundance that are consistent with limited mixing between regions.

Smith et al (2008) compared otolith micro-chemistry (multi-element chemistry and stable isotopes) and meristics (e.g., fin counts) from 0-group kahawai from two regions (Okahu Bay, Waitemata Harbour and Hakahaka Bay, Port Underwood). Two distant sites were chosen in order to provide the best chance of successful discrimination. Neither meristics nor stable isotopes provided any discrimination and magnesium and barium concentrations provided only weak discriminatory power.

On balance it seems possible that there are least two stocks of kahawai (*A. trutta*) within New Zealand waters with centres of concentration around the Bay of Plenty and the northern tip of the South Island. These two areas could be assumed to be separate for management purposes. Tagging data show that there is some limited mixing between these areas. Due to the shared QMA boundaries in the lower North Island and South Island, there is likely to be more mixing between the southern KAH QMAs than with the northern QMA (KAH 1).

There is no information about stock structure of *A. xylabion*.

4. STOCK ASSESSMENT

In 2007 an age-structured stock assessment was undertaken for KAH 1 using CASAL (Bull et al 2004). This assessment is reported below. This replaces the 1997 nationwide assessment which is no longer considered valid by the PELWG due to the simplistic methods used and its historical nature. Therefore, aside from some catch curve estimates of Z from the early 1990s, there is no longer an accepted stock assessment for areas outside KAH 1.

4.1 KAH 1

4.1.1 Estimates of catch, selectivity and abundance indices

(i) Commercial catch

The commercial catch history assumed in the assessment is provided in Table 9. It is noted that catches in the early years are less certain due to reporting issues (e.g., see Table 3 legend).

KAHAWAI (KAH)

(ii) Recreational catch

The recreational catch history in KAH 1 is poorly known. Estimates are available for the Hauraki Gulf in 2003–04 (Hartill et al 2007b) and for three subregions of KAH 1 in 2004–05 (Hartill et al 2007c) which were derived from aerial overflight surveys. These estimates are used in the model for those years.

Two recreational catch scenarios were ultimately considered in the stock assessment model: a constant harvest of either 800 t or 1865 t, except in 2005 when 530 t was used. The 530 t estimate was considered implausibly low as a long term average from 1975 so an arbitrary value of 800 t was used instead. The arbitrary upper bound of 1865 t is equal to the recreational allowance made when kahawai was introduced to the QMS 1 October 2004. This was based on the 2000 harvest estimate reduced by 15%.

Constant harvest tonnages were used as there was concern that if a catch history with an assumed trend was used this trend could influence the model results, despite being essentially unknown. It was felt that these two scenarios would span the likely impacts of intermediate catch scenarios, even those with a trend.

Data from three recent surveys of recreational fishers were used to apportion the annual harvests across the three subregions (Northland, Hauraki Gulf, and Bay of Plenty). These surveys were the two linked telephone diary surveys conducted in 1999–00 (Boyd & Reilly 2002) and 2000–01 (Boyd et al 2004) and the aerial overflight survey conducted in 2004–05 (Hartill et al 2007c). All three surveys suggest very similar catch split proportions: Northland 22%, the Hauraki Gulf 18%, and the Bay of Plenty 60%.

The time series of catches used was assumed to cover both recreational and non-commercial customary catch.

Table 9: Commercial catch time series used in the stock assessment. PS - purse seine, SN - set net, ST - single trawl, OT - other gears.

(iii) Catch composition data and selectivity estimates

The earliest catch-at-age data that are available were collected from commercial fisheries in 1991, 1992 and 1993. Landings were sampled from the East Northland purse seine fishery and from the Bay of Plenty single trawl and purse seine fisheries. These age distributions were included in the model with the exception of the 1993 Bay of Plenty purse seine data, which were dropped because they were shown to be unrepresentative of the landings. Age compositions for purse seine landings from east Northland and the Bay of Plenty were available for 2005 and included in the model. Age and length samples from the recreational fisheries in three regions of KAH 1 were available since 2001, and were also included in the model (Armiger et al 2006, Hartill et al 2007a, 2007d).

Selectivity ogives are estimated for each of the six fisheries (i.e., the three regional recreational fisheries, two regional purse seine fisheries, and a single trawl fishery), accounting for a high proportion of the KAH 1 landings in each year. A double normal selectivity ogive was used to describe the set net fishery, which, although it has relatively low landings (200–300 t in most years) compared to the purse seine fishery, has been included so that the associated indices of abundance can be used in the model. No landings have been sampled from this fishery, so the selectivities were not informed by any data.

(iv) Catch-curve analysis results

Annual estimates of total mortality (Z) have been derived from recreational catch data sampled in East Northland and the Bay of Plenty. They were calculated using a Chapman Robson estimator independently from the stock assessment model (Table 10). These estimates were calculated using a range of assumed ages for full recruitment to demonstrate the sensitivity of the results to this assumption.

Table 10: Estimates of Z derived from recreational catch sampling in KAH 1, by survey year by assumed age at recruitment.

East Northland		2001	2002	2003	2004	2005	2006	2007	2008
Age at recruitment									
3		0.33	0.33	0.32	0.28	0.24	0.28	0.28	0.24
4		0.34	0.38	0.35	0.31	0.28	0.32	0.23	0.28
5		0.30	0.37	0.39	0.33	0.33	0.35	0.35	0.33
6		0.30	0.40	0.41	0.38	0.36	0.41	0.41	0.34
Bay of Plenty									
3		0.23	0.25	0.28	0.20	0.27	0.24	0.24	0.24
4		0.26	0.30	0.32	0.23	0.29	0.27	0.27	0.27
5		0.28	0.33	0.34	0.26	0.30	0.24	0.24	0.29
6		0.30	0.36	0.38	0.32	0.30	0.26	0.26	0.29

(v) Indices of abundance

For the 2007 assessment, regional indices of abundance were available from two sources: recreational fisheries and set net fisheries (Figure 3). Two other indices of abundance were also initially considered from the Bay of Plenty, but dropped: an aerial sightings index, and one based on commercial trawl catch rate data. The former was considered underdeveloped and the latter was based on poor measures of catch and effort. In 2012, an aerial sightings index for the Bay of Plenty was developed and accepted by the working group (see below).

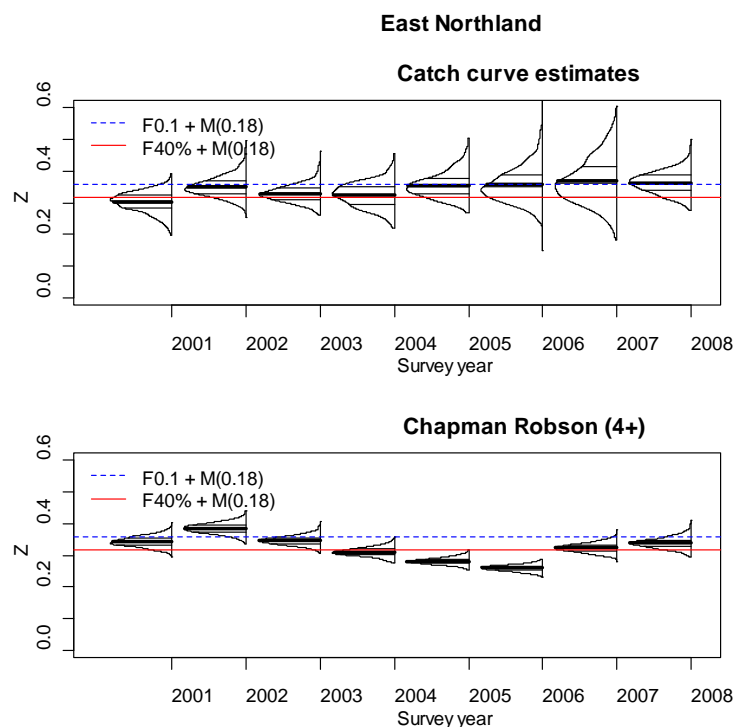

Figure 2: The distribution of bootstrap estimates of total mortality (Z) by survey year for East Northland (top two panels) and the Bay of Plenty (lower two panels). Theoretical optimal levels of Z derived from the YPR and SPR curves calculated in Hartill et al (2008) are denoted as horizontal lines for reference purposes (from Armiger et al 2009)

Boat ramp surveys have been conducted in KAH 1 since 1991, and these data have been used to generate standardised CPUE indices for three regional fisheries: East Northland, Hauraki Gulf and Bay of Plenty (Hartill & Walsh 2005). These indices were derived from Poisson-based generalised linear models of the number of kahawai caught in a trip (including those released) given the time spent fishing and other explanatory variables. Poisson-based modelling accommodates a high proportion of zero catches in the data, and posterior statistical tests suggested that the level of dispersion was close to one. Boat ramp data suggest that approximately 80% of the recreational catch is landed (Hartill & Walsh 2005).

Standardised indices of abundance were also derived from commercial set net data reported on CELR forms since 1990 (Figure 3). Generalised log-linear models were used to derive indices for each of the three sub-regions of KAH 1 (McKenzie et al 2007). There were insufficient data available from the Bay of Plenty to provide reliable indices for 2003–04 and 2004–05 so these years were not included in the model. Some PELWG members expressed their concerns at the utility of the set net indices, given the low catches taken by this method, the lack of an appropriate selectivity ogive, the potential for non-reporting of catch; and given that kahawai were not in the QMS for most of the series; and that it is only mandatory to report the top five species in a fishing event.

There is no consistent pattern in catch rates when comparisons are made across and within regions. Recreational catch rates in East Northland increased in the early 1990s, and then declined in recent years, whereas the reverse trend is evident in the set net index. Both indices exhibit interannual variability in the Hauraki Gulf and little trend is apparent. In the Bay of Plenty there is no trend in the recreational index, but a clear decline is evident in the set net index.

Aerial Sightings Index

In 2012, an index of abundance [sightings per unit effort (SPUE)] based on commercial aerial sightings data was accepted by the Northern Inshore Working Group. This index was calculated using data from the Ministry for Primary Industries database *aer_sight* and applying a generalised additive model (GAM) to produce standardised annual relative abundance indices (Taylor Draft).

Flights were restricted to those that were exclusive to the Bay of Plenty (BoP) (i.e., those having flight paths that remained within an area defined as the BoP), only flown by pilot #2 and were the first flight of the day (apart from some defined exceptions, e.g., short refuelling flights at the start of the day).

Estimates of relative year effects were obtained using a forward stepwise GAM, where the data were fitted using two models: 1) the probability of a flight having a positive sighting modelled using a binomial regression; and 2) the tonnage sighted on positive flights modelled using a lognormal regression. These two models were combined into a single index. The data used for the SPUE analyses consisted of aerial sightings of kahawai, trevally, jack mackerel, blue mackerel, and skipjack tuna collected over the period 1986–87 to 2010–11, with missing years in 1988–89, from 1994–95 to 1996–97 and in 2006–07. Most of these missing years were the result of there being no available data. By contrast, 2006–07 was dropped because the working group identified a bias in the annual index for that year because of the low number of available flights. The first year of the original series (1985–86) was dropped by the working group for the same reason.

Daily purse-seine catch for the vessels with which the pilot was working in the BoP was used as a proxy for target species. Catch data before 1989 were from the *fsu-new* database and data from 1989 to 2011 were from the *warehou* database.

The Working Group concluded that the combined model of SPUE for kahawai is probably a reasonable index of abundance in the BoP. The index should be used in a stock assessment, using diagnostics to gauge the quality of the abundance index.

The BoP combined SPUE index for kahawai shows substantial inter-annual variation with an overall gradual declining trend from 1986–87 to 2002–03; thereafter increasing sharply to a peak in 2007–08, and then declining to points above the long-term mean (Table 11, Figure 3).

Table 11: Standardised SPUE indices for KAH 1 from the binomial-lognormal model fitted to the series 1986–87 to 2010–11 with years of missing data shown.

Fishing year	Lognormal	Binomial	Combined
1986–87	1.01	0.81	1.22
1987–88	0.9	1.13	0.89
1988–89	No data	No data	No data
1989–90	0.6	0.9	0.61
1990–91	0.62	0.9	0.82
1991–92	0.8	0.84	0.68
1992–93	1.12	1.12	1.25
1993–94	1.57	1.01	1.2
1994–95	No data	No data	No data
1995–96	No data	No data	No data
1996–97	No data	No data	No data
1997–98	0.84	0.94	0.92
1998–99	0.45	1.16	0.48
1999–00	0.54	0.71	0.51
2000–01	0.75	1.08	0.73
2001–02	0.6	1.1	0.68
2002–03	0.54	0.85	0.38
2003–04	1.41	1.12	1.36
2004–05	1.83	1.1	1.78
2005–06	1.9	1.15	2.06
2006–07	Insufficient data	Insufficient data	Insufficient data
2007–08	2.06	1.12	2.59
2008–09	1.92	0.93	1.28
2009–10	1.6	1.07	1.57
2010–11	1.38	1.16	1.65

Figure 3: Standardised sightings per unit effort indices for the Bay of Plenty KAH 1 stock, derived as a combination of year effect estimates from a lognormal and a binomial regression. Vertical lines are the 95% confidence interval.

4.1.2 Model structure

The stock assessment was restricted to KAH 1, because this is the QMA where most of the observational data have been collected. Future assessments may consider a broader stock definition, but improved understanding of the movement dynamics of this species and further development of this model are required before this can be attempted. Even within KAH 1 there is little information on connectivity between the three main areas of the fishery: East Northland, Hauraki Gulf and the Bay of Plenty. Annual sampling of recreational catches, which has taken place in all three areas since 2001 (and intermittently since 1991), suggests that there are consistent regional differences in the length and age compositions of kahawai among these regions. For example, in the Hauraki Gulf, recreational landings of kahawai are regularly dominated by three year olds, with low proportions of fish older than five years. It is improbable that these regional differences in age structure can be attributed to relative fishing pressure alone, which suggests that some form of movement between areas is highly likely. There are few tag data available that can be used to estimate these migration processes, because almost all of the kahawai that have been tagged have been released in the Bay of Plenty. This provides little information about emigration from the Hauraki Gulf and from East Northland. For this reason it was not possible to partition the model into three interconnected sub-stocks, as their connectivity is inestimable. Area specific observational data were combined into a single stock model which includes most of the currently available data.

In the stock assessment model it is assumed that KAH 1 is a single biological stock, exploited by several fisheries. Deviations from the spawner recruitment curve were estimated for those years when there were three or more years of observational catch-at-age data, and were constrained to a mean of 1.0 across all fishing years from 1974–75 to 2005–06.

A single annual time step was used, in which ageing was followed by recruitment, maturation, growth, and then mortality (natural and fishing). The relationships between length and age, and length and weight, were both assumed to be constant through time and were based on the parameter values given in Table 8. Annual abundances of the age classes 1 to 20 were estimated in the model, with 20 year olds representing all fish older than 19 years. The model was not sex specific. Maturation was knife edged at four years of age. There is no information on the relationship between stock size and recruitment, and the rate of natural mortality is uncertain. Sensitivity to these parameters is discussed in the next section.

It was assumed that the population was at an unfished equilibrium state (B_0) in 1975. Key model outputs are probably robust to this assumption as commercial landings were only of the order of a few hundred

tonnes and recreational landings were assumed to be low relative to stock size prior to this time. Total fishing mortality was apportioned between fisheries (combinations of method and region) according to observed catches and estimated selectivities. Method specific annual landings from five fishing methods were considered: recreational, purse seine, single trawl, set net, and other minor commercial fisheries. Landings by method are further divided into regional catch histories, as the catch-at-age data were collected at this spatial scale. Purse seine fisheries only occur in East Northland and the Bay of Plenty and share a common estimated selectivity. Separate selectivities were fitted to each of the three regional recreational fisheries.

4.1.3 Evaluation of uncertainty

A common approach in the assessment of fish stocks is to select a ‘base’ or ‘reference’ model which represents the most likely situation and then to evaluate uncertainty by selecting a number of analyses which vary key assumptions relative to the base case model. Frequently the more important sets of runs are evaluated using Bayesian methods to characterise the uncertainty in the estimated and derived parameters.

In the assessment for KAH 1 there was uncertainty in some important model inputs (e.g., recreational catch history and abundance indices) and some influential biological parameters could not be estimated within the model (e.g., natural mortality and steepness).

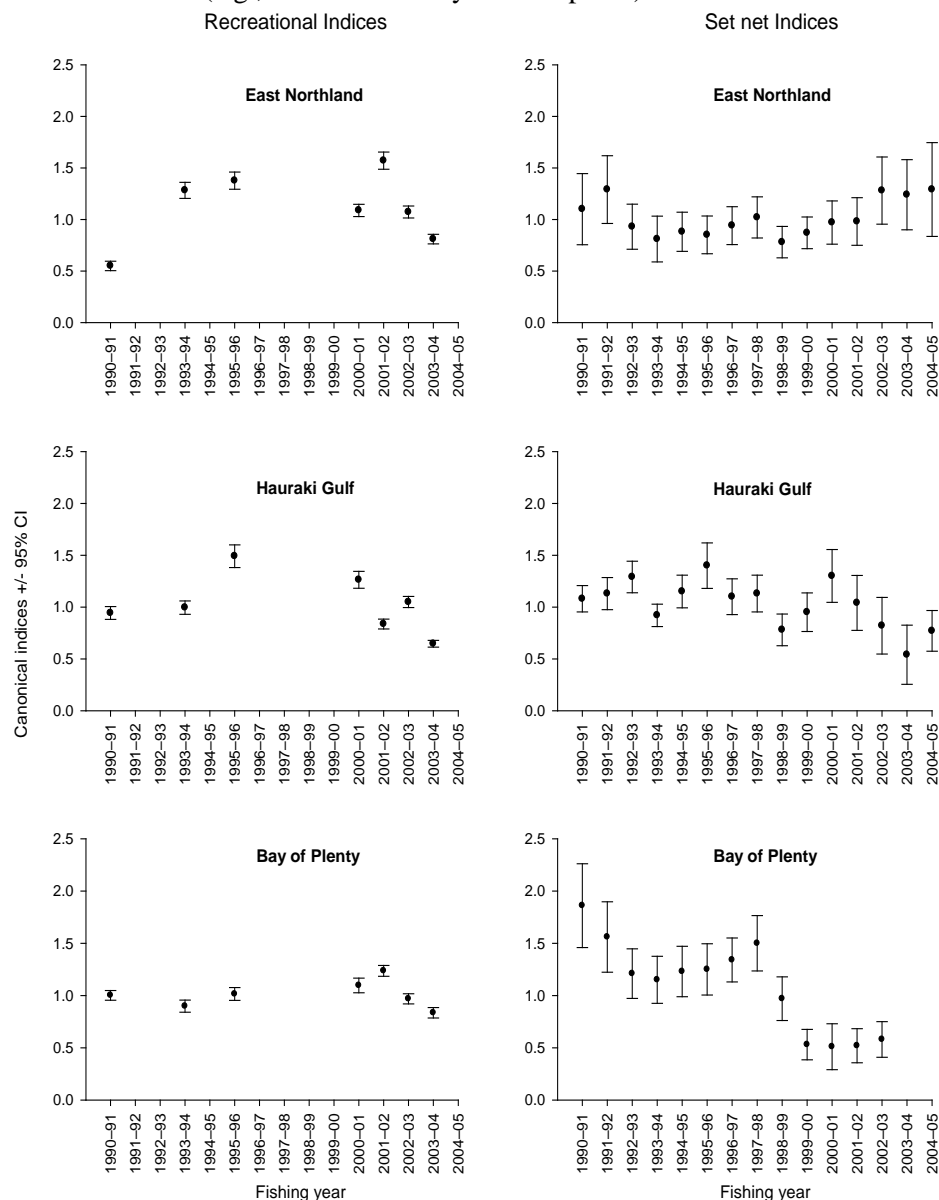

Figure 4: Standardised regional catch rate indices considered in the KAH 1 stock assessment model. Indices derived from recreational fishers using baited hooks and/or jigs since 1991 are given in the left hand panels, and those derived from commercial set net CELR data are given in the right hand panels.

The approach taken to represent uncertainty was to determine the four main factors for which uncertainty was likely to have an impact on key model outputs (referred to as the ‘axes of uncertainty’) and then to select a limited number of plausible options across each axis. Model runs were then undertaken for all possible combinations of options across each axis - this set of options was referred to as the ‘grid’. The selected grid axes are provided in Table 12. Overall, the grid comprised 36 model runs which in totality were thought to be a realistic reflection of the extent of uncertainty in the KAH 1 assessment.

Table 12: Axes of uncertainty and options chosen on grid. *N* is the number of levels on the axis.

Axis	N	Range
<i>M</i>	3	0.12, 0.18, 0.24
H	2	0.75, 1
Non-commercial catch	2	Constant 800, 1865 t
Abundance indices	3	All, no set net, no recreational

In relation to the selected grid chosen, it was noted that:

- with additional time and resources the number of axes and/or levels in the grid could be increased;
- model diagnostics were not examined for all grid runs;
- the lower and higher values of *M* used in the grid (0.12 and 0.24) were probably at the limit of what would be considered plausible values;
- if this approach were to be developed further, it would be useful to weight each grid cell based on the plausibility of the cell components. This was not done for this exercise; and
- the range of values selected for recreational catch may not span the plausible range - a lower plausible value was not included in the grid because it was not likely to lead to qualitatively different conclusions.

4.1.4 Results

A grid search of the four axes of uncertainty suggested that there were differences in the magnitude and manner of their influence on the model. The model was largely insensitive to the indices of abundance offered, which is to be expected given the contradictory nature of these indices. The assumed steepness of the stock recruitment relationship also had only small influence on estimates of fishing mortality and yield.

Natural mortality had the most influence on the results. As mentioned in the previous section, both the lower value of 0.12 and the upper value of 0.24 were regarded as being at the limit of plausible values. Lower values of natural mortality resulted in higher levels of estimated fishing mortality, lower yields, and lower current biomass, although there was little contrast in estimates of virgin biomass (Figures 5 and 6, Table 13). Increased levels of natural mortality were offset by estimated selectivity ogives which were shifted to the right, resulting in reduced fishing mortality. The model essentially operated as an integrated catch curve, in which the slope of the right hand limb of the age distributions was approximated by the model parameters and dynamics.

The second most influential axis of uncertainty was the axis relating to the assumed recreational catch history (Figures 5 and 6, Table 13). The assumed recreational catch history had little influence on the predicted stock status (B_{06}/B_{MSY}), but did affect the estimate of total available yield.

Table 13: Model outputs for different values of *M* and assumed non-commercial catches. Values represent the median of the six model runs in each stratum (abundance index and steepness choice). All biomass estimates are in terms of spawning biomass.

		B_0 (t)	B_{06} (t)	B_{06}/B_0	B_{06}/B_{MSY}	MSY (t)
800 t	0.12	41 690	11 260	0.27	1.22	2 130
	0.18	38 762	17 582	0.45	1.84	2 822
	0.24	43 216	27 228	0.62	2.12	4 007
1865 t	0.12	59 453	14 518	0.24	1.11	3 042
	0.18	54 614	22 562	0.43	1.78	4 004
	0.24	60 082	35 882	0.59	2.06	5 564

Estimates of B_{MSY} as a proportion of B_0 varied across model runs (18.3–31% B_0). Lower percentages were associated with higher values of steepness.

Based on the scenarios examined, it is likely that current spawning biomass is greater than B_{MSY} , but it is uncertain how far above.

4.1.5 Yields

A modified yield per recruit analysis (incorporating the impact of the stock recruitment relationship) was carried out for each scenario to calculate the equilibrium yield estimates within each grid cell. It was assumed that the maximum sustainable yield (MSY) occurs at the maximum yield per recruit ($F = F_{max}$). B_{MSY} was defined as the start of the year biomass producing the maximum yield with fixed selectivities for each method and fixed proportions of the catch for each method based on the catch distribution in 2005–06. Results are expressed relative to virgin start of year biomass (B_0 ; which is sensitive to the assumed recreational catch history). The yield per recruit and its maximum will vary depending on the allocation of total catch amongst the fishing methods, because yield is mediated through the selectivity curves and these differ among the fisheries.

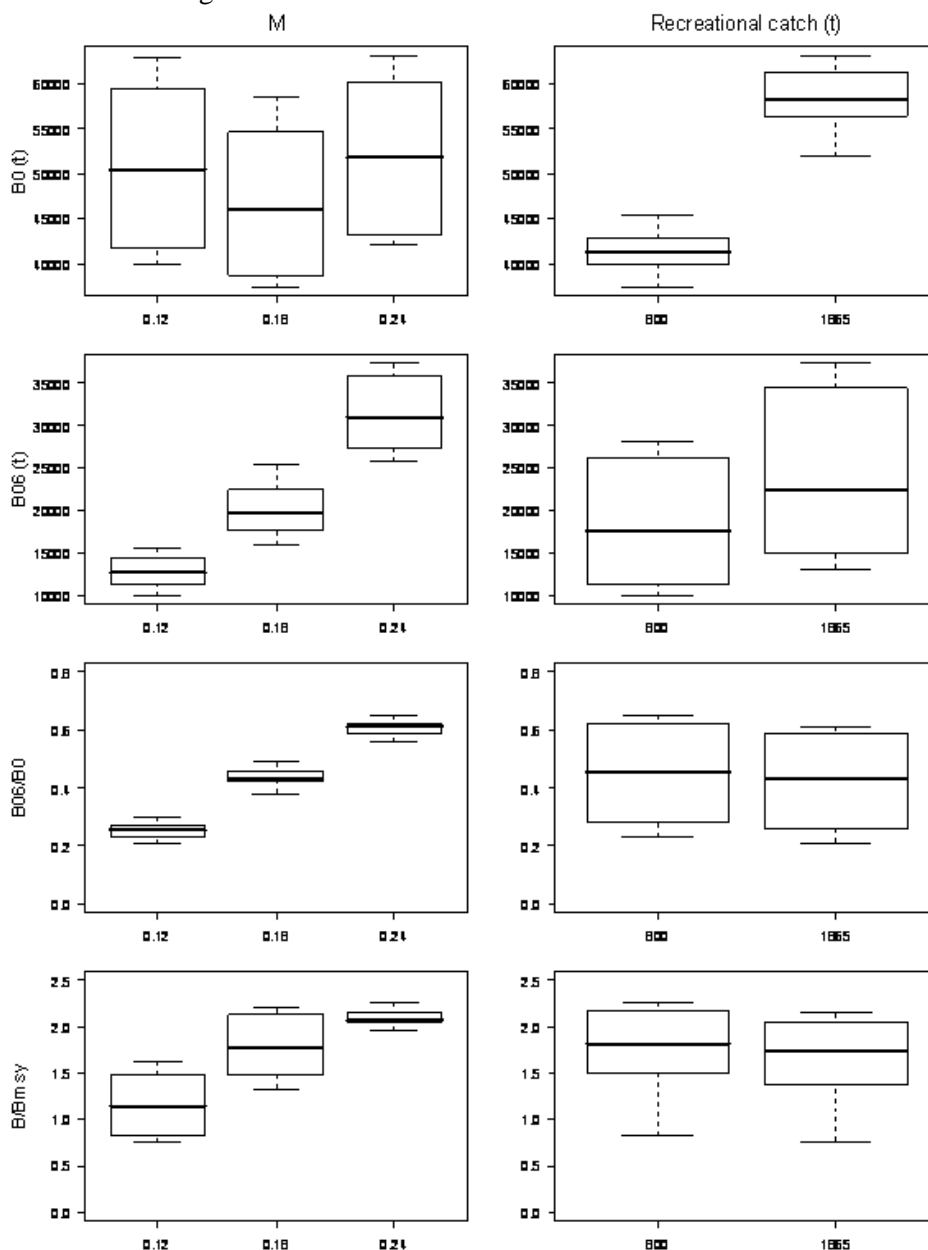

Figure 5: Boxplot showing the distribution of model results for the two key axes in the grid: natural mortality (left) and non-commercial catches (right). Each boxplot summarises 12 and 18 model runs for natural mortality and non-commercial catches respectively.

KAHAWAI (KAH)

Estimates of MSY (t) derived from differing combinations of M and assumed recreational catch history are given in Table 13 and Figure 7. Differences in the range of MSY tonnages associated with the two recreational catch history scenarios (Figure 7) are almost solely due to the size of the associated estimates of B_0 . That is, the ratio between MSY and B_0 is approximately constant across the range of recreational harvest estimates. For this reason, the yield estimates are only valid for each matched recreational harvest estimate. The assumed natural mortality rate also influences the yield estimate, both in an absolute sense, and relative to B_0 .

Current assumed removals are lower than almost all estimates of deterministic MSY . Combining this with the result that most estimates of B_{06} are well above B_{MSY} it is unlikely that the stock will decline below B_{MSY} at current assumed catch levels, given the model recruitment assumptions.

The current TAC for KAH 1 is 3315 t with a TACC and allowances outlined in Table 1. The estimates of deterministic MSY depend on model assumptions, in particular the assumed natural mortality and time series of non-commercial catches. When non-commercial harvests are assumed to have been 800 t per year, median MSY estimates from grid strata range from 2130 to 4007 t. When non-commercial harvests are assumed to have been 1865 t per year, median MSY estimates from grid strata range from 3042 to 5564 t.

Figure 6: Biomass trajectories for differing assumed values for natural mortality (M), stock recruitment steepness (h) and assumed recreational catch history. For a given M , the upper pair of trajectories relate to a recreational catch of 1865 tonnes per annum, and the lower pair 800 tonnes. For each pair of trajectories, the upper is based on a steepness of 0.75 and the lower an assumed value of 1.0. The model did not appear to be sensitive to the indices of abundance used, and both the set net and recreational indices of abundance are included in these runs.

Figure 7: Boxplot showing the distribution of MSY estimates for the two key axes in the grid: natural mortality (left) and non-commercial catches (right). Each boxplot summarises 12 and 18 model runs for natural mortality and non-commercial catches respectively.

4.2 Assessment for other KAH areas

Historic estimates of total mortality (Z) derived from the age composition of commercial catch data collected in the early 1990s for areas outside KAH 1 are given in Table 14.

Table 14: Estimates of Z derived from commercial fisheries catch sampling data.

Fishstock	Estimate	Time sampled	Source
KAH 2	0.24	Nov 92	Drummond (1995)
KAH 3 (Marlborough Sounds)	0.22–0.35	Nov 90–Mar 91	Drummond & Wilson (1993)
KAH 3 (Cloudy/Clifford Bays)	0.19–0.27	Nov 90–Jun 91	Drummond & Wilson (1993)
KAH 3 (Kaikoura)	0.23–0.30	Nov 90–May 91	Drummond & Wilson (1993)
KAH 9	0.11	Feb 91–Mar 91	Jones et al (1992)

The interpretation of catch curve analyses is difficult for schooling pelagic species for several reasons which include: (a) difficulties in obtaining a representative sample of sufficient size to describe the age distribution of the population because of the schooling behaviour; (b) uncertainty in the value of M ; and (c) lack of contrast in the data if exploitation rates are not changing.

5. STATUS OF THE STOCKS

KAH 1

Stock Structure Assumptions

Two stocks of kahawai (*A. trutta*) are assumed to exist within New Zealand waters with centres of concentration around the Bay of Plenty and the northern tip of the South Island. Tagging data show that there is limited mixing between these areas.

Stock Status	
Year of Most Recent Assessment	2007: Stock Assessment 2009: Catch curve analysis
Assessment Runs Presented	Thirty six models were run which encompassed plausible values for several poorly understood model inputs (e.g., recreational catch history, abundance indices, natural mortality and the spawner recruitment relationship).
Reference Points	Target: Not established but B_{MSY} assumed. Estimates of B_{MSY} as a proportion of B_0 varied across the 36 model runs (18.3–31% B_0) Soft Limit: 20% B_0 Hard Limit: 10% B_0
Status in relation to Target	Based on the scenarios examined, it is Likely (> 60%) that the 2006 spawning biomass was at or above B_{MSY} , but it is uncertain how far above
Status in relation to Limits	Soft Limit: Unlikely (< 40%) to be below Hard Limit: Very Unlikely (< 10%) to be below

Historical Stock Status Trajectory and Current Status

Biomass trajectories for differing assumed values for natural mortality (M), stock recruitment steepness (h) and assumed recreational catch history. For a given M , the upper pair of trajectories relate to a recreational catch of 1865 tonnes per annum, and the lower pair 800 tonnes. For each pair of trajectories, the upper is based on a steepness of 0.75 and the lower an assumed value of 1.0. The model did not appear to be sensitive to the indices of abundance used, and both the setnet and recreational indices of abundance are included in these runs.

Fishery and Stock Trends

Recent Trend in Biomass or Proxy	For M greater than 0.12 spawning biomass is estimated to have declined gradually from 1975 to 1990, to have increased somewhat from 1991 to 1995 and to have remained relatively stable until the end of the assessment period in 2007. For $M = 0.12$ spawning biomass declines continuously through the assessment period.
Recent Trend in Fishing Mortality or Proxy	A time series of total mortality estimates for East Northland and the Bay of Plenty from 2001 to 2008, based on recreational catch-at-age data, suggests that there has been little change in fishing mortality over this period. Estimates of total mortality were at or below that associated with $F_{SB40\%}$, suggesting that fishing mortality was at or below F_{MSY} .
Other Abundance Indices	There is no consistent pattern in catch rates when comparisons are made across and within regions.
Trends in Other Relevant Indicators or Variables	-

Projections and Prognosis

Stock Projections or Prognosis	Deterministic projections assuming $M = 0.18$ and including all abundance indices were undertaken in 2008 based on the 2007 assessment. These indicated that biomass was predicted to increase for all scenarios over the next five years.
Probability of Current Catch or TACC causing decline below Limits	Current assumed removals are lower than almost all estimates of deterministic MSY . Combining this with the result that most estimates of B_{06} are well above B_{MSY} , it is Unlikely that the stock will decline below B_{MSY} at current assumed catch levels. Soft Limit: Unlikely (< 40%) Hard Limit: Very Unlikely (< 10%)

Assessment Methodology

Assessment Type	Level 1 - Quantitative stock assessment Level 2 - Total mortality analysis
Assessment Method	Statistical catch at age model implemented under CASAL. For the

	mortality analysis regression methods and the Chapman-Robson estimator were used.	
Main data inputs	<ul style="list-style-type: none"> - Proportions-at-age data from recreational fishery and commercial purse-seine fishery data - Estimates of biological parameters (e.g. growth, age-at-maturity and length/weight) - Standardized CPUE indices of abundance from recreational line and commercial set-net fishery - Estimates of M - Estimates of steepness for the stock-recruit relationship - Estimates of recreational harvest - Commercial catch 	
Period of Assessment	Latest assessment: Level 1: 2007 Level 2: 2009	Next assessment: 2014
Changes to Model Structure and Assumptions	This was a new model.	
Major Sources of Uncertainty	Estimates of M , steepness, recreational harvest and degree of mixing between Bay of Plenty, Hauraki Gulf and East Northland.	

Qualifying Comments

The Northern Inshore Working Group reviewed estimates of KAH 1 recreational harvest in 2010 and concluded that, of the two estimates used in the stock assessment, the 800 t estimate was more plausible.

Fishery Interactions

Commercial catches of KAH 1 are primarily taken by purse-seine in association with jack mackerel, blue mackerel and trevally.

All other KAH regions

No accepted assessment is available that covers these regions. It is not known if the current catches, allowances or TACCs are sustainable. The status of KAH 2, 3 and 8 relative to B_{MSY} is unknown.

TACCs and reported landings for the 2012–13 fishing year are summarised in Table 15.

Table 15: Summary of reported landings (t) and TACCs by QMA for the most recent fishing year.

Fishstock	FMA	2012–13 TACC	2012–13 Reported landings
KAH 1	1	1 075	1 095
KAH 2	2	705	502
KAH 3	3, 5, & 7	410	195
KAH 4	4	9	0
KAH 8	8 & 9	520	468
KAH 10	10	9	0
TOTAL		2 728	2 260

KINA (SUR)

(Evechinus chloroticus)

Kina

1. FISHERY SUMMARY

South Island kina was introduced into the Quota Management System in October 2002. North Island kina was introduced into the Quota Management System from October 2003. Five Quota Management Areas based on the FMAs 3, 4, 5, 7A (Marlborough Sounds) and 7B (west coast) were created in the South Island, and current allowances, TACCs, and TACs are summarised in Table 1. Seven Quota Management Areas based on the FMAs 1A (Auckland-North), 1B (Auckland-South), 2A (Central (East-North)), 2B (Central (East-South)), 8, 9 and 10 were created in the North Island, and the current allowances, TACCs and TACs are summarised in Table 2. The historical landings and TACC values for the main SUR stocks are depicted in Figure 1.

Table 1: Recreational and customary non-commercial allowances, TACCs and TACs (t) for kina Fishstocks 3, 4, 5, and 7 for the latest fishing year.

Fishstock	Recreational Allowance	Customary non-commercial Allowance	Other Mortality Allowance	TACC	TAC
SUR 3	10	10	1	21	42
SUR 4	7	20	3	225	255
SUR 5	10	10	5	455	480
SUR 7A	20	80	3	135	238
SUR 7B	5	10	1	10	26

Table 2: Recreational and customary non-commercial allowances, TACCs and TACs (t) for kina Fishstocks 1,2,8,9 and 10 for the latest fishing year.

Fishstock	Recreational Allowance	Customary non-commercial Allowance	Other Mortality Allowance	TACC	TAC
SUR 1A	65	65	2	40	172

SUR 8	12	12	1	1	26
SUR 9	11	11	1	10	33
SUR 10	0	0	0	0	0

1.1 Commercial fisheries

Most kina are found in waters less than 10 m deep and are harvested by breath-hold diving, although about 10% of the total catch in 1998–99 was by taken by dredge in SUR 7. Some target dredging also occurs in SUR 7. There is no minimum legal size for kina. Almost all of the roe harvested in this

KINA (SUR)

fishery is consumed on the domestic market. In 1988–89, competitive TACCs were established in the more important FMAs but not in east Northland (SUR 1) or at the Chatham Islands (SUR 4), both of which developed into productive fisheries in the 1990s (Table 3). On 1 October 1992 the Ministry of Fisheries placed a moratorium on the issue of permits to commercially harvest kina. The kina fishery has evolved considerably since the imposition of the moratorium. Where present, the competitive TACCs were either not caught or were exceeded, both by wide margins. Much of the increase in catch observed in SUR 5 in the early 1990s can be attributed to an experimental fishery developed in SUR 5, between Puysegur Point and Breaksea Island. The short-lived Kina Development Programme harvested kina from Dusky Sound in 1993 under special permit.

Table 3: Total reported catch (t greenweight) of kina (SUR) by FMA and fishing year by all methods and target species.

Data from 1989 and 1990 are combined from the FSU and CELR databases. – indicates no recorded catch. Data for the period 1983 to 1999 are from Andrew (2001), and have been groomed. Catch estimates for 2000 and 2001 are taken directly from MFish. * includes 133 t caught in Dusky Sound experimental fishery. Catches from SUR 6, 8, and 9 have been pooled because too few permit holders recorded catches in these FMAs to report them singly.

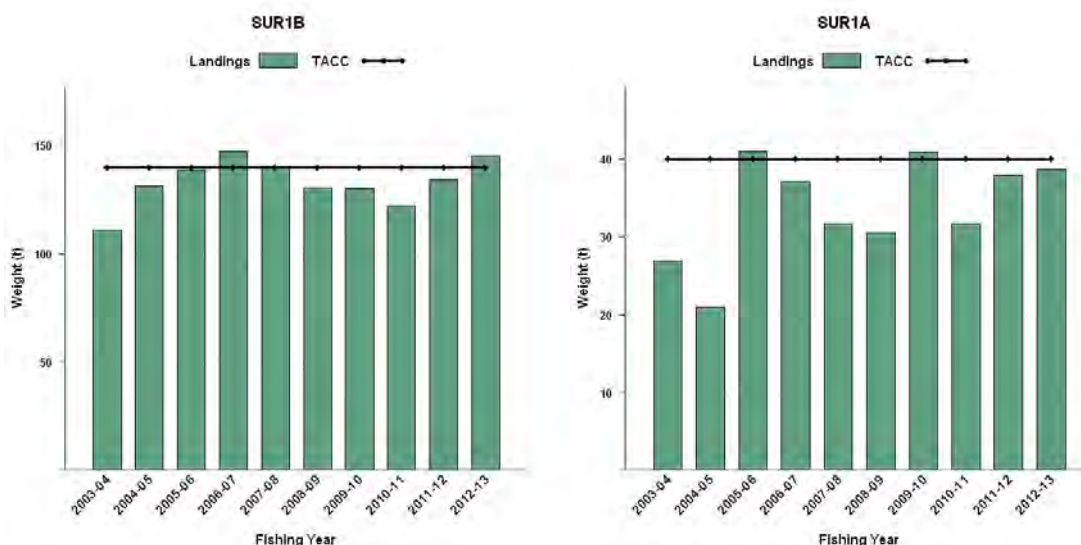

Figure 1: Historical landings and TACC for the nine main SUR stocks. From left to right: SUR 1A (Northland) and SUR 1B (Hauraki Gulf, Bay of Plenty). [Continued on next page].

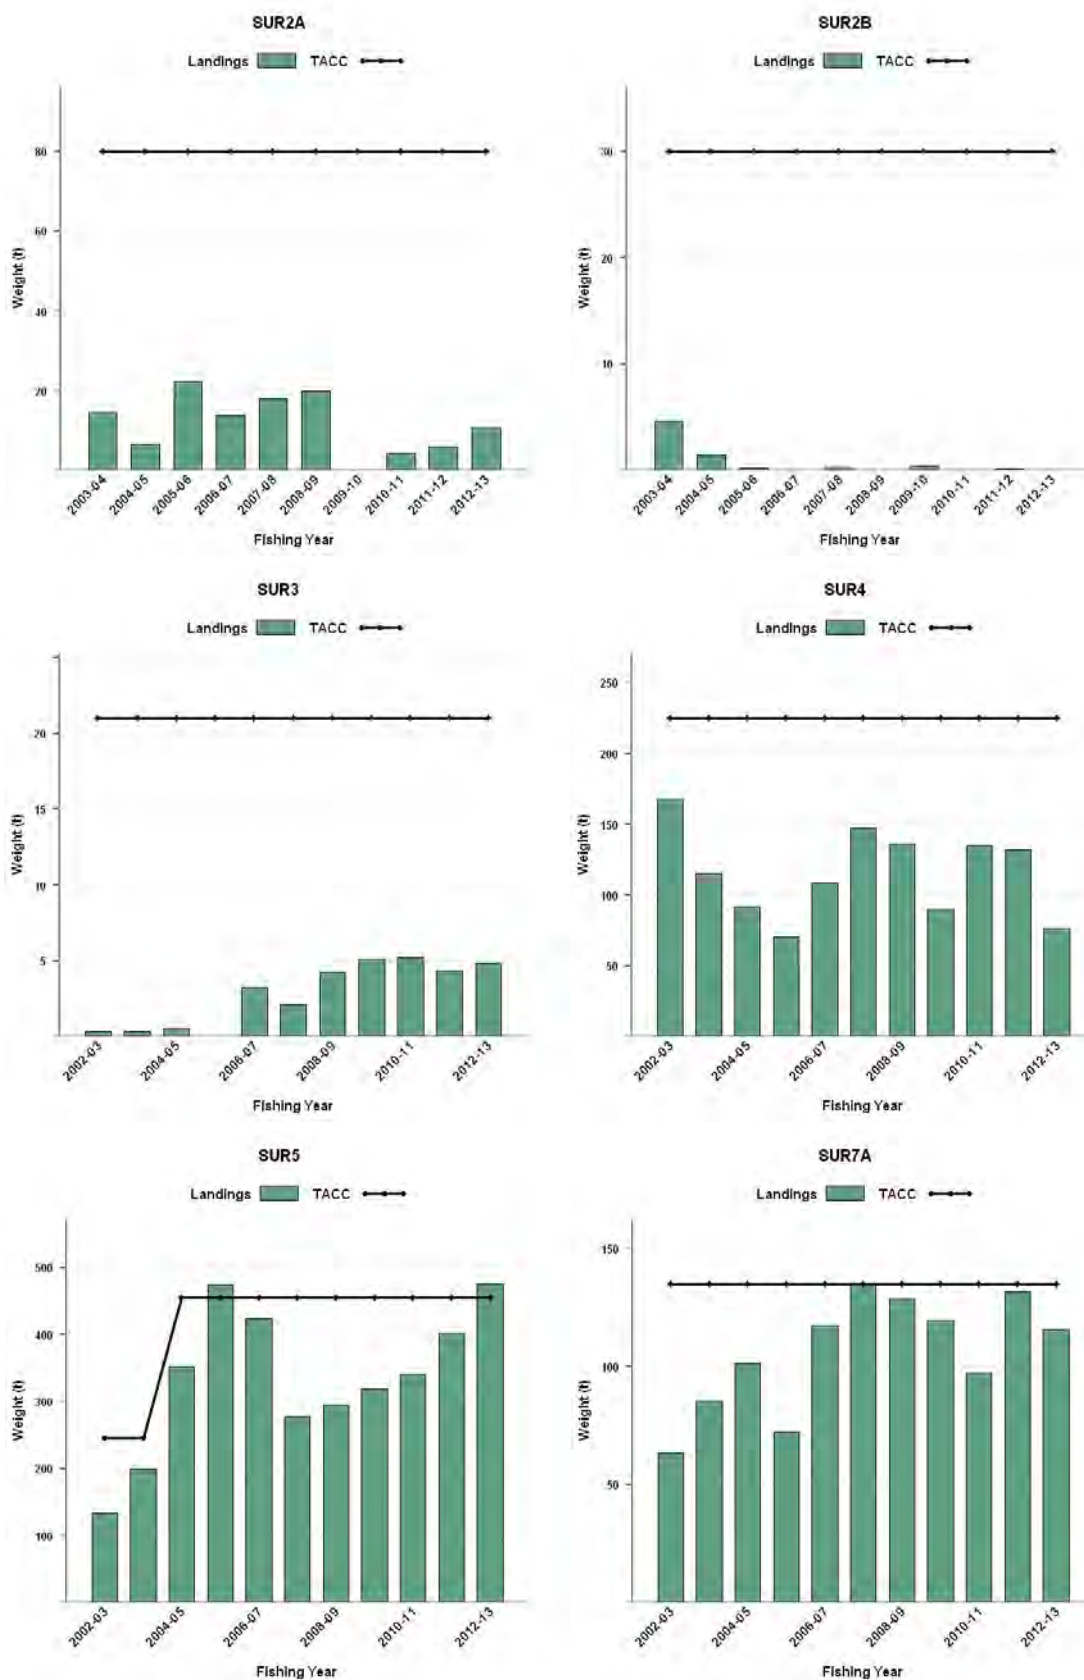

Figure 1 [Continued]: Historical landings and TACC for the nine main SUR stocks. From top left: SUR 2A (East Coast), SUR 2B (Wairarapa, Wellington), SUR 3 (South East Coast), SUR 4 (South East Chatham Rise), SUR 5 (Southland), and SUR 7A (Challenger Nelson Marlborough) [Continued on next page].

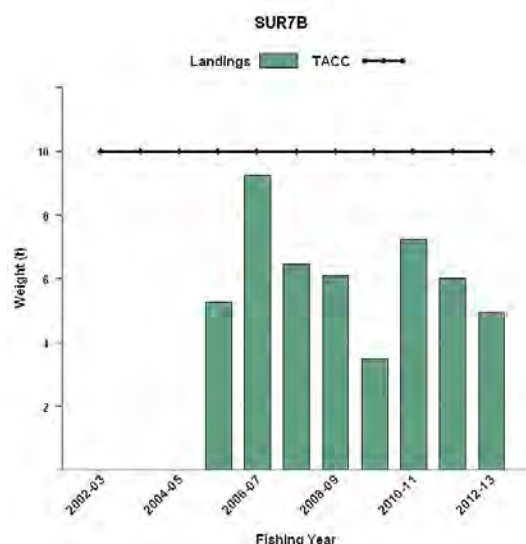

Figure 1 [Continued]: Historical landings and TACC for the nine main SUR stocks. Here: SUR 7B (Challenger Westland). Note that these figures do not show data prior to entry into the QMS.

1.2 Recreational fisheries

Recreational catch was estimated in a national survey in 1996 (Fisher & Bradford 1998, Bradford 1998) and 2000 (Boyd & Reilly 2002, Boyd et al 2004) (Table 4). There are no estimates of recreational catch from the Chatham Islands. In many instances, insufficient kina were caught to provide reliable estimates of the error associated with the estimates of total harvest. The recreational harvest estimates for 1996 are not considered reliable as estimates of total harvest but provide relative estimates between areas. The harvest estimates for 2000 are considered to be more reliable as absolute estimates with the exception of SUR 2.

1.3 Customary non-commercial fisheries

There is an important customary non-commercial harvest of kina by Maori for food. Where data are available, only small catches of kina have been reported under the customary non-commercial harvest provisions of the Fisheries Act 1996. In SUR 3, 5, and 7, all catches were less than 1 t per year (Table 5). These catch estimates are probably under-estimates as an unknown proportion of the kina harvested by Maori is caught outside of Taiapure or Mataitai and not recorded as customary non-commercial harvest (P. Grimshaw, Ngai Tahu Development Corporation, pers. comm.). No data are available for other regions of New Zealand (S. Kerins, Te Ohu Kai Moana, pers. comm.).

Table 4: Recreational harvest of kina for 1993–94 and 1996.

Area	Number of kina ($\times 1\,000$)	CV (%)	Catch (t)*
1993–94			
East Northland	109	60	27.1
Hauraki Gulf	14	-	3.5

SUR 7	2	101	0.5
SUR 8	85	85	21.1
SUR 9	82	67	20.4

CVs are indicated only for those samples with adequate sample sizes. Data compiled from Bradford (1998) and Fisher & Bradford (1998).

Catches in numbers have been converted to catch in tonnes by assuming an average whole weight of 248.3 g per kina. In the absence of size-specific catch statistics, a parsimonious conversion assumes that kina are caught in equal proportion across a size range of 60 to 110 mm TD. The lower size in this range is approximately the size-at-maturity (see Barker 2001) and the upper size is close to maximum harvested size. Weight-at-size was calculated using a test diameter-weight relationship ($W = (6.27 \times 10^{-4})TD^{2.88}$) derived for kina of 60–110 mm TD from Dusky Sound ($n = 1063$, unpublished data). The estimates of total catch in tonnes should be considered as indicative only.

Table 5: Reported customary catch by FMA for SUR 3, 5, and 7.

Year	SUR	Count	Weight (kg)
1998–99	3	100	25
	5	1 522	433
	7	0	0
1999–2000	3	0	0
	5	1 631	405
	7	0	0

Data as numbers caught supplied by Ngai Tahu Development Corporation. Catch in kilograms was estimated using the conversion rules described in the paragraph above.

1.4 Illegal catch

Current levels of illegal harvest are not known.

1.5 Other sources of mortality

Although there is no minimum legal size for kina, some incidental mortality is likely because roe quality (recovery rate and colour) is commonly assessed by opening ‘test’ kina underwater. These animals are not subsequently landed. There are no estimates of the magnitude to this incidental mortality.

2. BIOLOGY

The biology and ecology of kina has been extensively studied; this literature has most recently been reviewed by Barker (2001). *Evechinus chloroticus* is found throughout New Zealand and the sub-Antarctic Islands. Kina has an annual reproductive cycle which culminates in spawning between November and March (Dix 1970, Walker 1984, McShane et al 1994 & 1996, Lamare & Stewart 1998, Lamare 1998). Size at maturity appears to vary considerably and may be as small as 30 mm and as large as 75 mm TD (Dix 1970, Barker et al 1998). In Dusky Sound, kina are reproductively mature at 50–60 mm T.D. (McShane et al 1996). Within these seemingly consistent patterns in the seasonality of the reproductive cycle there are many differences in the gonad size at small spatial scales.

Settlement is likely to be vary between years and appears to differ among locations and habitats (Dix 1972, Walker 1984). Laboratory work has shown that kina larval mortality increased with increasing concentrations of suspended sediment at realistic concentrations (Phillips & Shima 2006). In the field, but not in the laboratory, development abnormalities were found associated with suspended sediment concentrations, this suggests the importance of other environmental factors associated with terrestrial runoff (Schwarz et al 2006). Juvenile settlement and mortality has also been observed to increase with sediment at realistic concentrations in a size-specific manner in the laboratory; this agrees with juvenile patterns of distribution observed in the field (Walker 2007). Few small kina were observed in any of the surveys in Dusky Sound (McShane et al 1993). These results suggest that the productivity of stocks in Fiordland may be low and that recruitment over-fishing is a real possibility.

There is relatively little information available on the interactions between kina and its predators and competitors. Although a wide range of fish and invertebrates eat kina, there is limited evidence that these species control or limit populations of kina in Fiordland. Work in a marine reserve, where large predators such as reef fishes and crayfish are abundant, indicates that predators can control numbers of kina surviving the transition from crevice-bound to open substratum grazing (Cole & Keuskamp 1998, Babcock et al 1999). Babcock et al (1999) have drawn a direct link between the increases in snapper and crayfish populations and the long-term decline in kina populations in the Leigh Marine

KINA (SUR)

Reserve. There is however, no evidence that high kina densities limit rock lobster populations (Andrew & MacDiarmid 1991). It is likely, however, that changes in the abundance of kina, and the consequent changes in habitat representation, are part of a complex set of interacting processes, including but not exclusively, increased predation.

Kina compete with a range of invertebrate herbivores, including paua. There is no published evidence that high densities of kina limit paua populations in Fiordland. McShane (1997) reported that paua are abundant in Dusky Sound, and in Chalky and Preservation Inlets, but are rare in the fjords.

Lamare & Mladenov (2000) estimate that kina grow 8–10 mm in their first year of life. Growth rates will vary considerably depending on local conditions but kina may take 8–9 years to reach 100 mm TD, and very large individuals may reach ages of more than 20 years (Lamare & Mladenov 2000).

3. STOCKS AND AREAS

There appear to be few genetic differences in kina populations from Leigh (North Auckland) and Stewart Island (Mladenov et al 1997) which suggests that there is at least some mixing among populations. There is no direct evidence that populations of kina at the Chatham Islands differ genetically from those on the mainland, nor is there evidence that “populations” of kina at the Chatham Islands are dependent on the dispersal of larvae from the mainland.

4. STOCK ASSESSMENT

Although there is a wealth of information on the biology and ecology of this species (see Barker 2001 for reviews), there is relatively little that can be used to assess the status of exploited stocks. There have been no assessments of sustainable yield nor are there estimates of biomass or trends in relative abundance for any Fishstock (Annala 1995).

4.1 Estimates of fishery parameters and abundance

Andrew (2001) reported catch rates from both dive and dredge fisheries but advised caution in the interpretation of catch rate information of sedentary invertebrates, like kina, gathered at broad spatial scales.

Indices of relative abundance using timed swims have been reported for Ariel Reef in SUR 2 (Anderson & Stewart 1993), Chatham Islands (Schiel et al 1995, Naylor & Andrew 2002), and D’Urville Island and Arapawa Island in SUR 7 (McShane et al 1994a). Numerous surveys of kina have been done over the last 30 years in fished areas, mostly by university-based researchers (e.g. Dix 1970, Choat & Schiel 1982, Schiel et al 1995, Cole & Keuskamp 1998, Babcock et al 1999, Wing et al 2001). Naylor & Andrew (2002) reported a range of densities for kina around Chatham Island from $0.17/\text{m}^2$ (northwest Chatham Island) to $1.6/\text{m}^2$ (south east Chatham Island). These were generally lower than estimates made in the mid 1990s by Schiel et al (1995) ($0.2/\text{m}^2$ to $6/\text{m}^2$). By contrast, even lower kina densities of around $0.1/\text{m}^2$ were reported by McShane et al (1994a) for both Arapawa and D’Urville Island. Dix (1970) reported much higher mean relatively high densities of kina ranging from $2.2/\text{m}^2$ in Queen Charlotte Sound to $6/\text{m}^2$ at Kaikoura.

4.2 Biomass estimates

McShane & Naylor (1993) reported biomass estimates of 2500 and 500 t respectively for D’Urville and Arapawa Islands (SUR 7), presumably based on an expansion of density estimates reported in McShane et al (1994) by an area estimate, however, the methods are not detailed.

Biomass was estimated for Dusky Sound and Chalky Inlet (SUR 5) prior to Dusky Sound being opened as an experimental fishery in May 1993 (McShane & Naylor 1991, 1993). Productivity and biomass was to be estimated by depletion methods but this was unsuccessful because only 133 t of the projected 1000 t was caught (McShane et al 1994b) and this catch was insufficient to cause a measurable change in the estimated biomass of kina.

4.3 Yield estimates and projections

MCY has not been estimated for any SUR fishstock. Within SUR 5, an *MCY* estimate of sustainable yield within Dusky Sound and Chalky Inlet was reported in Annala (1995). This estimate used Method 1 of Annala (1995) for new fisheries based on surveys done by McShane & Naylor (1991, 1993) and an estimate of a reference fishing mortality derived from McShane et al (1994a). The estimated annual sustainable yield of 275 t for these two areas has never been harvested because they are closed to commercial fishing except under special permit.

CAY has not been estimated for any SUR fishstock.

5. STATUS OF THE STOCKS

For all Fishstocks it is not known if current catch levels or TACCs are sustainable, or if they are at levels which will allow the stocks to move towards a size that will support sustainable yields.

KING CRAB (KIC)

(*Lithodes murrayi*, *Neolithodes brodiei*)

1. FISHERY SUMMARY

1.1 Commercial fisheries

King crabs (*Lithodes murrayi* and *Neolithodes brodiei*) were introduced into the Quota Management System on 1 April 2004 with a combined TAC of 9 t and TACC 9 t (Table 1). There are no allowances for customary, recreational or other sources of mortality. The fishing year is from 1 April to 31 March and commercial catches are measured in greenweight. The two crabs are relatively distinct, and are found at different depths, but may be confused with other species of *Lithodes*.

Landings have been reported from all QMAs except KIC 7 and KIC 9, however these landings are small and are unlikely to reflect the real catch as these crabs are generally discarded at sea and remain unreported. Most of the landed catch has been reported under the aggregated code KIC, although there are a few records by species (i.e., *L. murrayi* [LMU] and *N. brodiei* [NEB]).

Figure 1: Historical landings and TACC for KIC 4 (South East Chatham Rise). Note that this figure does not show data prior to entry into the QMS.

KING CRAB (KIC)

Most of the reported landings since 1992–93 are from KIC 6, and most of this was landed in the 1996–97 fishing year under a special permit. Between 2000 and 2002 landings were also made under a special permit (Table 1). Target fishing is by potting, although the crabs are taken as bycatch in the orange roughy fishery off the Wairarapa coast and in Queen Scallop dredging off the Otago coast. Figure 1 shows the historical landings and TACC for KIC 4.

1.2 Recreational fisheries

There are no records of recreational use of these crabs, and because of their depth range recreational catch is unlikely.

1.3 Customary non-commercial fisheries

There are no known records of customary use of these crabs, and because of their depth range customary take is unlikely.

1.4 Illegal catch

There is no known illegal catch of these crabs.

1.5 Other sources of mortality

There is no quantitative information on other sources of mortality, although the crabs are sometimes taken as a bycatch in orange roughy fishing and queen scallop fishing.

Table 1: TACCs and reported landings (t) of king crab by Fishstock from 1992–93 to 2012–13 from CELR and CLR data. [Continued on next page].

*In 1995–96 and 1998–99, 47 kg and 1 kg of LMU were landed respectively, but no FMA was assigned to the landings. In 1996–97 24 kg of NEB was landed but no FMA was assigned to this landing. These reported landings by species are included in the total landings for KIC in those years.

2. BIOLOGY

King crabs belong to the infra order *Anomura*, and differ from true crabs (*Brachyura*) in that the last pair of walking legs is reduced and folded inside the carapace.

L. murrayi is a large, pear-shaped, dark purplish-red or brick red crab that has been found at depths between 120 m and 700 m. from the east coast of Northland to southern parts of the Campbell Plateau. It is a circumpolar, Southern Ocean species growing so large that the distance between the tips of the second legs can reach 1.25 m. The carapace width in males of this species may exceed 200 mm. Females are smaller.

N. brodiei is also pear-shaped, and typically a uniform brick to bright red colour. It is widely distributed from the Three Kings Islands to the Campbell Plateau, where it occurs on soft and rocky bottom between about 800 and 1100 m. Carapace width in this species is up to about 180 mm.

King crabs are thought to aggregate for protection during breeding and moulting. Migrations between shallow and deep waters also probably occur in response to moulting and mating, at least in near-shore populations. They occur mainly on soft substrates but have also been found on rocky bottoms. They are probably omnivorous, although animal food (sessile, sedentary, and mobile invertebrates, and small fish), including dead material, is their predominant food. Their principal predators are fish and seals.

Sexes are separate in all species of king crabs and they appear to be seasonal spawners, probably spawning in summer or autumn.

3. STOCKS AND AREAS

For management purposes stock boundaries are based on FMAs, however, there is currently no biological or fishery information which could be used to identify stock boundaries.

KING CRAB (KIC)

4. STOCK ASSESSMENT

4.1 Estimates of fishery parameters and abundance

There are no estimates of fishery parameters or abundance for any king crab fishstock.

4.2 Biomass estimates

There are no biomass estimates for any king crab fishstock.

4.3 Yield estimates and projections

There are no estimates of *MCY* and *CAY* for any king crab fishstock.

5. STATUS OF THE STOCKS

There are no estimates of reference or current biomass for any king crab fishstock.

KINGFISH (KIN)*(Seriola lalandi)*

Haku

**1. FISHERY SUMMARY**

Kingfish were introduced into the QMS on 1 October 2003, with allowances, TACCs and TACs in Table 1 except that the TACC for KIN 8 was increased from 36 to 45 t in October 2012.

Table 1: Recreational and customary non-commercial allowances, TACCs and TACs by Fishstock.

KIN 10	1	0	0	1	2

An increased minimum legal size (MLS) to 75 cm (from 65 cm) for recreationally caught kingfish was introduced on 15 January 2004. Kingfish were added to the 6th Schedule of the Fisheries Act (1996) in October 2005 for all fishing methods except setnet and in all areas. A special reporting code for 6th Schedule releases was introduced on 1 October 2006 to allow monitoring of releases. Kingfish released in accordance with 6th Schedule conditions and reported against this code are not counted against ACE.

KINGFISH (KIN)

Figure 1: Historical landings and TACC for the three largest KIN stocks. From top left: KIN 1 (Auckland East), KIN 2 (Central East) and KIN 8 (Central Egmont).

1.1 Commercial fisheries

Kingfish commercial landings are reported largely as bycatch of inshore setnet, trawl and longline fisheries. From 1991 to late 2003, targeting of kingfish (as a non-QMS species) was prohibited unless the species was identified on a fisher's permit. A few permit holders were authorized to target kingfish and most of their catch was taken using setnets.

Commercially, kingfish is a moderately high value species and is usually sold as fillets or whole chilled. The main fishing areas for kingfish are the east (KIN 1 and KIN 2) and west coast (KIN 8) of the North Island of New Zealand (Table 2). The largest commercial catches generally come from KIN 1. Landings were relatively large in 1983–84, especially in KIN 1, and were probably due to the greater number of vessels in the fishery prior to the introduction of the QMS in 1986. In addition, there was increased effort and better reporting as fishers sought to establish a catch history for the main species in anticipation of the introduction of the QMS. By 1988–89, reported catches of kingfish had reduced to their lowest levels across most areas. This was most likely due to the under-reporting of less common species in the catch (which includes kingfish) and the introduction of non-QMS restrictions. An increase in kingfish landings in FMA 1 between 1988–89 and 1992–93 and in FMA 2 between 1988–89 and 1991–92 may be due to a number of factors. These include: better reporting of catches; changes in fishing patterns with increased catch by setnet; increased numbers of vessels reporting kingfish catch; and increased targeting of kingfish.

The total reported catch across all FMAs peaked in 1992–93 at 532 t, with 73% of the catch from KIN 1. By 1993–94, the reported catch of kingfish over all QMAs decreased considerably, mainly because of the reduced catch from KIN 1. Possible reasons for this decrease include: the effect of the October 1993 introduction of a MLS of 65 cm on all methods other than trawl; changes in fishing patterns in the snapper and trevally target setnet, trawl, and bottom longline fisheries (that were responsible for most of the non-target catch of kingfish); decreased target fishing for kingfish; and setnet area closures in FMA 1 from October 1993. The trawl exemption with respect to MLS was removed in December 2000.

The annual catch of kingfish from KIN 1 fluctuated between 100 and 250 t from 1993–94 through to 2000–01 and has remained below 100 t since 2001–02. The kingfish annual catch from KIN 2 declined from the high of 120 t in 1995–96 to 50 t in 2003–04, and has mostly been below 60 t since then. Landings from KIN 8 have averaged approximately 35 t for the last 19 years, with catches ranging from 19–70 t. In 2002–03 landings nearly triple the 2001–02 level were reported in KIN 8, the highest ever landing in this area. Landings returned to near average in 2003–04 and 2004–05, but were still above the TACC. Annual catches in KIN 8 have remained below 50 t since 2005–06, but were often above the 36 t TACC. Although the TACC was increased to 45 t in October 2011 to accommodate previous levels of by-catch, the 2011–12 commercial catch increased substantially to 92 t. In addition to annual catches reported for kingfish QMAs, about 5 t of kingfish has been taken by New Zealand flagged vessels fishing outside NZ fishing waters.

Assuming that kingfish targeting effectively ceased during the mid 1990s, catches since the early 2000s possibly reflect ‘true’ bycatch levels.

Table 2: Reported landings (t) of kingfish by area (QMA) from 1983–84 to 2012–13. From 1986–87 to 2000–01, total landings are from LFRRs and landings by QMA are from CLRs prorated to the LFRR total. Totals include landings not attributed to the listed QMAs. MHR data from 2001–present. [Continued next page].

* FSU data (Area unknown data prorated in proportion to recorded catch).

§ Some data included in FMA 1.

1.2 Recreational fisheries

Kingfish is highly regarded by recreational fishers in New Zealand for its sporting attributes and large size. Kingfish are most often caught by recreational fishers from private boats and from charter boats, but are also a prized catch for spearfishers and shore based game fishers. Kingfish are recognized internationally as a sport fish, and kingfish caught in New Zealand waters hold 20 of the 22 International Gamefish Association World Records.

1.2.1 Management controls

The main methods used to manage recreational harvests of kingfish are minimum legal size limits (MLS), method restrictions and daily bag limits. Fishers can take up to three kingfish as part their daily bag limit and the MLS is 75 cm.

Recreational fishers have voiced concerns over a perceived marked decline in the size of kingfish available to them in recent years. Many clubs, competitions and charter boats have implemented a voluntary one kingfish

per person per day limit in response. A number of gamefish clubs have also adopted a minimum size limit of 100 cm for kingfish.

1.2.2 Estimates of recreational harvest

Recreational catch estimates are given in Table 3. There are two broad approaches to estimating recreational fisheries harvest: the use of onsite or access point methods where fishers are surveyed or counted at the point of fishing or access to their fishing activity; and, offsite methods where some form of post-event interview and/or diary are used to collect data from fishers.

The first estimates of recreational harvest for kingfish were calculated using an offsite approach, the offsite regional telephone and diary survey approach. Estimates for 1996 came from a national telephone and diary survey (Bradford 1998). Another national telephone and diary survey was carried out in 2000 (Boyd & Reilly 2005) and a rolling replacement of diarists in 2001 (Boyd & Reilly 2004) allowed estimates for a further year (population scaling ratios and mean weights were not re-estimated in 2001).

The harvest estimates provided by these telephone diary surveys are no longer considered reliable for various reasons. With the early telephone/diary method, fishers were recruited to fill in diaries by way of a telephone survey that also estimates the proportion of the population that is eligible (likely to fish). A “soft refusal” bias in the eligibility proportion arises if interviewees who do not wish to co-operate falsely state that they never fish. The proportion of eligible fishers in the population (and, hence, the harvest) is thereby under-estimated. Pilot studies for the 2000 telephone/diary survey suggested that this effect could occur when recreational fishing was established as the subject of the interview at the outset. Another equally serious cause of bias in telephone/diary surveys was that diarists who did not immediately record their day’s catch after a trip sometimes overstated their catch or the number of trips made. There is some indirect evidence that this may have occurred in all the telephone/diary surveys (Wright et al 2004).

The recreational harvest estimates provided by the 2000 and 2001 telephone diary surveys are thought to be implausibly high for many species, which led to the development of an alternative maximum count aerial-access onsite method that provides a more direct means of estimating recreational harvests for suitable fisheries. The maximum count aerial-access approach combines data collected concurrently from two sources: a creel survey of recreational fishers returning to a subsample of ramps throughout the day; and an aerial survey count of vessels observed to be fishing at the approximate time of peak fishing effort on the same day. The ratio of the aerial count in a particular area to the number of interviewed parties who claimed to have fished in that area at the time of the overflight was used to scale up harvests observed at surveyed ramps, to estimate harvest taken by all fishers returning to all ramps. The methodology is further described by Hartill et al (2007).

This aerial-access method was first employed and optimised to estimate snapper harvests in the Hauraki Gulf in 2003–04. It was then extended to survey the wider SNA 1 fishery in 2004–05 and to provide estimates for other species, including kingfish. The PELWG indicated that the kingfish estimate should be considered with considerable caution due to the limited overlap between this methods sampling technique and the fisheries for kingfish, e.g., the target fisheries for kingfish are usually in offshore areas from launches which were not sampled by the boat ramp survey. For this reason the results from this survey have not been accepted or included in the working group report at this time.

In response to the cost and scale challenges associated with onsite methods, in particular the difficulties in sampling other than trailer boat fisheries, offsite approaches to estimating recreational fisheries harvest have been revisited. This led to the development and implementation of a national panel survey for the 2011–12 fishing year. The panel survey used face-to-face interviews of a random sample of New Zealand households to recruit a panel of fishers and non-fishers for a full year. The panel members were contacted regularly about their fishing activities and catch information collected in standardised phone interviews. Note that the national panel survey estimate does not include harvest taken on recreational charter vessels, or recreational harvest taken under s111 general approvals.

KINGFISH (KIN)

Table 3: Recreational harvest estimates for kingfish stocks. The telephone/diary surveys ran from December to November but are denoted by the January calendar year. The national panel survey ran through the October to September fishing year but is denoted by the January calendar year. Mean fish weights were obtained from boat ramp surveys (for the telephone/diary and panel survey harvest estimates). (Source: Tierney et al 1997, Bradford 1997, Bradford 1998, Boyd & Reilly 2002, MPI unpublished data).

#No harvest estimate available in the survey report, estimate presented is calculated as average fish weight for all years and areas by the number of fish estimated caught.

All indications are that the recreational catch is in the range of 500–700 t in KIN 1. The earlier telephone/diary surveys and the recent national panel survey also indicate that over 85% of the recreational kingfish catch is taken in the northern QMAs (1 & 8).

It was assumed that the introduction of the higher MLS of 75 cm on 15 January 2004 for kingfish would reduce recreational catches.

1.3 Customary non-commercial fisheries

Kingfish is an important traditional food fish for Maori, but no quantitative information on the level of Maori customary non-commercial catch is available. The extent of the traditional fisheries for kingfish in the past is described by the Muriwhenua Fishing Report (Waitangi Tribunal 1988). Because of the coastal distribution of the species and its inclination to strike lures, it is likely that historically Maori caught considerable numbers of kingfish.

1.4 Illegal catch

There is no known illegal catch of kingfish.

1.5 Other sources of mortality

The extent of any other sources of mortality is unknown, however, handling mortality for sub-MLS size fish is likely to occur in both the recreational (sub 75 cm) and commercial (sub 65 cm) fisheries.

2. BIOLOGY

In New Zealand, kingfish are predominantly found in the northern half of the North Island but also occur from 29° to 46° S, Kermadec Islands to Foveaux Strait (Francis 1988) and to depths of 200 m. Kingfish are large predatory fish with adults exceeding one and a half metres in length. They usually occur in schools

ranging from a few fish to well over a hundred fish. Kingfish tend to occupy a semi-pelagic existence and occur mainly in open coastal waters, preferring areas of high current and or tidal flow adjacent to rocky outcrops, reefs and pinnacles. However, kingfish are not restricted to these habitats and are sometimes caught or observed in open sandy bottom areas and within shallow enclosed bays.

Estimates of age have been derived from opaque-zone counts in sagittal otolith thin sections. Estimates of kingfish von Bertalanffy growth parameters were also derived from recreational tagging data and otoliths collected from the eastern Bay of Plenty. Estimates of K and L_{∞} were similar being 0.128 and 130 cm from the otolith age data and 0.130 and 142 cm from the tagging increment data respectively (Table 4). The hard-structure ageing techniques have yet to be validated for New Zealand kingfish, although the position of the first annulus has been validated using regular samples of 0+ year old fish from a fish aggregating device (Holdsworth et al 2013; Francis et al 2005).

A Bayesian analysis of length and maturity data suggests that the length of 50% maturity is 97 cm in females and 83 cm in males.

The recent research has provided estimates of M ranging from 0.20–0.25, however, these estimates are thought to represent an upper bound as the samples were taken from an exploited population.

Available biological parameters relevant to stock assessment are shown in Table 4.

3. STOCKS AND AREAS

A study based on meristic characters and parasite loads suggests two stocks of kingfish off the west and east coasts. These stocks are contained within the Tasman current on the west coast and the east Auckland current and east Cape current on the east coast, with little mixing between them. The east coast stock may be further subdivided into northeast and Hawkes Bay stocks based on limited exchange from tagging studies and parasite marker prevalence.

Tagging results suggest that most adult kingfish do not move outside local areas, with many tag returns close to the release site. However, some tagged kingfish have been found to move very long distances; there are validated reports of New Zealand tagged kingfish being caught in Australian waters and Australian tagged kingfish being recaptured in New Zealand waters.

4. STOCK ASSESSMENT

4.1 Estimates of fishery parameters and abundance

Total mortality (Z) was estimated for kingfish stocks in East Northland and in the Bay of Plenty based on the age structure of the recreational catches in 2010 (Holdsworth and Saul 2010). In the Bay of

KINGFISH (KIN)

Plenty estimates of Z for offshore (i.e., White Island) and inshore samples were 0.3 and 0.38, respectively; assuming an age of full recruitment of 5 yrs. Assuming an instantaneous rate of natural mortality (M) of 0.2, the target reference point of $F_{40\%}$ for kingfish in KIN 1 was calculated to be 0.1. This suggests that overfishing of kingfish in the Bay of Plenty is not occurring.

Total mortality for East Northland was estimated to be 0.77. However, fishing pressure is expected to be lower in East Northland than in the Bay of Plenty and since no samples were obtained from offshore areas known to be inhabited by large kingfish – i.e. Three Kings Islands and Ranfurly Bank – the Northern Inshore Working Group concluded that the recreational catch sampled in 2010 was unlikely to reflect the age structure of the entire East Northland population. As the 2010 estimate of Z for East Northland may well have been biased (high) by emigration to offshore areas, this estimate is considered to be unreliable.

4.2 Biomass estimates

Few kingfish are encountered in trawl surveys, suggesting that trawling is not a suitable method for monitoring changes in kingfish abundance. Kingfish are amenable to mark-recapture studies. However, up to now, tagging studies have been conducted solely to describe kingfish movement patterns and to estimate growth. Data from these programmes is inadequate to estimate stock biomass.

4.5 Yield estimates and projections

No information is available.

4.6 Other factors

Kingfish in New Zealand can be regarded as a high value species from customary, commercial and recreational perspectives. Although fluctuating, catches of kingfish have shown very little trend over the last 20 years and there is no direct evidence to suggest that the current catch levels are not sustainable. However, recreational fishers are concerned about a perceived decline in the quality of the fishery.

5. STATUS OF THE STOCKS

Stock Structure Assumptions

The movement of New Zealand kingfish has been extensively studied through mark-recapture programmes. Although some kingfish moved considerable distances (e.g., from New Zealand to Australia) most kingfish were recaptured close to the site of release, regardless of time at liberty. It is therefore assumed that New Zealand kingfish are comprised of several biological stocks. In addition to the results from tagging studies, the age structure of recreational catches suggests that kingfish off East Northland and in the Bay of Plenty in KIN 1 comprise separate stocks.

Fishery Interactions

Commercial kingfish catch is almost all bycatch in fisheries for other species.

Research Needs

Future kingfish catch at age sampling in KIN 1 needs to include samples from offshore fishing grounds.

CPUE based on charterboat catch and effort forms should be investigated once there are sufficient data.

KINGFISH (KIN)

● KIN 1 – East Northland

A status of the stock summary table is not included for the East Northland substock as the 2010 estimates of mortality (*Z*) for this area are not reliable.

Yields, TACCs and reported landings for the 2012–13 fishing year are summarised in Table 5.

Table 5: Summary of yields (t) from the commercial fishery, and reported commercial landings (t) for the most recent fishing year.

Fishstock	FMA	MCY	2012–13 Actual TACC	2012–13 Reported landings
KIN 1	Auckland (East)	1	195	88
KIN 2	Central	2	40	59
KIN 3	South-east (Coast), Southland, Sub-Antarctic	3, 5 & 6	-	2
KIN 4	South-east (Chatham)	4	-	< 1
KIN 7	Challenger	7	-	12
KIN 8	Central (West) and Auckland (West)	8 & 9	20	66
KIN 10	Kermadec	10	-	0
Total		260*	209	226

*5 ton MCY estimate for FMAs 3,4,5,6 & 7 combined included in total.

Knobbed Whelk (KWH)

Austrofusus glans

1. FISHERY SUMMARY

Knobbed whelks (*Austrofusus glans*) were introduced into the Quota Management System on 1 October 2006. The fishing year is from 1 October to 30 September and commercial catches are measured in greenweight. TACs have been allocated in 10 QMAs (Table 1). This species is managed under Schedule 6 of the Fisheries Act for all stocks, which allows for them to be returned to where they were taken (as soon as practicable after being taken) providing they are likely to survive.

Table 1: Current TAC, TACC and allowances for customary fishing, recreational fishing and other sources of mortality for *Austrofusus glans*.

QMA	TAC (t)	TACC (t)	Customary fishing	Recreational fishing	Other sources of mortality
KWH1	3	1	1	1	0

KWH 9	3	1	1	1	0
Total	88	67	10	10	1

1.1 Commercial fisheries

Target fishing for knobbed whelks is by baited pots. Because economic returns for whelk fishing are poor, most of the historical catch is bycatch from oyster and scallop dredging and from bottom trawling. Due to the low value of this species it is likely that there is a high level of unreported discarded catch.

Landings shown in Table 2 for the period 1990–91 to 2005–06 were recorded under the generic code for whelks (WHE), however the Ministry considers that in FMA 1, 2, 7, and 8, most reported landings were of the knobbed whelk *Austrofusus glans*. In FMA 3, 4, 5, and 6, the Ministry considers that about a third of reported landings were of the knobbed whelk, while the remainder were the large ostrich foot shell *Struthiolaria papulosa*.

Reported landings of knobbed whelk in FMA 1, FMA 2, and FMA 8 have been relatively low and variable since the 1990s and have been (largely or all) accounted for as bycatch. In FMA 7 in the early 1990s higher catches were reported as part of experimental fisheries in Golden and Tasman Bay to

KNOBBED WHELK (KWH)

provide stock assessment information in these areas (Tables 2 and 3). Landings are split into two tables (before and after the 2006 fishing year) as reporting requirements changed when knobbed whelks entered the QMS.

Table 2: Reported landings (t) of whelks (WHE) by FMA from 1990–91 to 2005–06 from landing returns. See section 1.1 for an explanation of the proportion of WHE that are considered to be knobbed whelks.

1.2 Recreational fisheries

There are no estimates of recreational catch.

1.3 Customary non-commercial fisheries

There are no estimates of current customary catch.

1.4 Illegal catch

There is no known illegal catch of this whelk.

1.5 Other sources of mortality

There is no information on other sources of mortality for this whelk.

2. BIOLOGY

The knobbed whelk *A. glans*, is a widely distributed gastropod found from low tide to about 600 m (Powell 1979). This carnivorous whelk grows up to 5 cm long, and occurs throughout New Zealand where it is found on sandy/silt/mud substrate. There is very little published about the biology of this species; most references are identification notes or records of occurrence. It is a scavenger that buries in the substrate when not feeding. A wide variety of invertebrates including polychaetes, gastropods, and bivalves occur within the wide depth range of the knobbed whelk, but no interdependent relationships are documented with *A. glans*.

3. STOCKS AND AREAS

For management purposes stock boundaries are based on FMAs. There is no biological information on stock structure, recruitment patterns, or other biological characteristics which might indicate alternative stock boundaries.

4. ENVIRONMENTAL AND ECOSYSTEM CONSIDERATIONS

This section has yet to be drafted and approved by the Aquatic Environment Working Group.

5. STOCK ASSESSMENT

5.1 Estimates of fishery parameters and abundance

There are no estimates of fishery parameters or abundance for any knobbed whelk fishstock.

5.2 Biomass estimates

There are no biomass estimates for any knobbed whelk fishstock.

5.3 Yield estimates and projections

There are no estimates of *MCY* for any knobbed whelk fishstock.

There are no estimates of *CAY* for any knobbed whelk fishstock.

6. STATUS OF THE STOCKS

LEATHERJACKET (LEA)

(*Meuschenia scaber*)
Kokiri, Hiriri

**1. FISHERY SUMMARY**

Leatherjacket was introduced into the QMS on 1 October 2003, with allowances, TACCs and TACs shown in Table 1.

Table 1: Recreational and Customary non-commercial allowances, TACCs and TACs for leatherjacket by Fishstock.

Fishstock	Recreational Allowance	Customary Non-Commercial Allowance	Other sources of mortality	TACC	TAC
LEA 1	5	1	9	188	203
LEA 2	2	1	57	1 136	1 196
LEA 3	2	1	5	100	108
LEA 4	1	1	1	7	10
LEA 10	0	0	0	0	0
Total	10	4		1 431	1 517

1.1 Commercial fisheries

Nationally, very small landings were first reported in 1948. Most of the current leatherjacket catch is taken as a bycatch, and it is very likely that leatherjacket has always been primarily a bycatch species. From only a few tonnes in the early 1960s, reported landings increased to 200–400 tonnes in the 1970s, 1980s and early 1990s (Table 2). Figure 1 shows the historical landings and TACC values for the main leatherjacket stocks. Landings increased further in the late 1990s to around 1000 to 1300 tonnes, but have decreased to less than 600 t in 2011–12. It is possible that actual catches were higher than reported prior to the 1970s, but that some catches were discarded without being reported due to low market demand in this period. On average over the last four years total landings have only been 41% of the TACC.

1.2 Recreational fisheries

The National Marine Recreational Fishing surveys in 1994, 1996 and 2000 do not provide an estimate of the non-commercial catches of leatherjacket because very few were caught. It is likely that recreational fishers, especially in the northern region, will have caught some leatherjacket by spear fishing, in rock lobster pots and setnets. Leatherjackets are seldom caught by hook and line.

LEATHERJACKET (LEA)

Table 2: Reported commercial landings (tonnes) of leatherjacket by fishstock for the fishing years from 1989–90 to 2012–13. Landings for LEA 10 have not been shown as these were negligible and were rounded to zero.

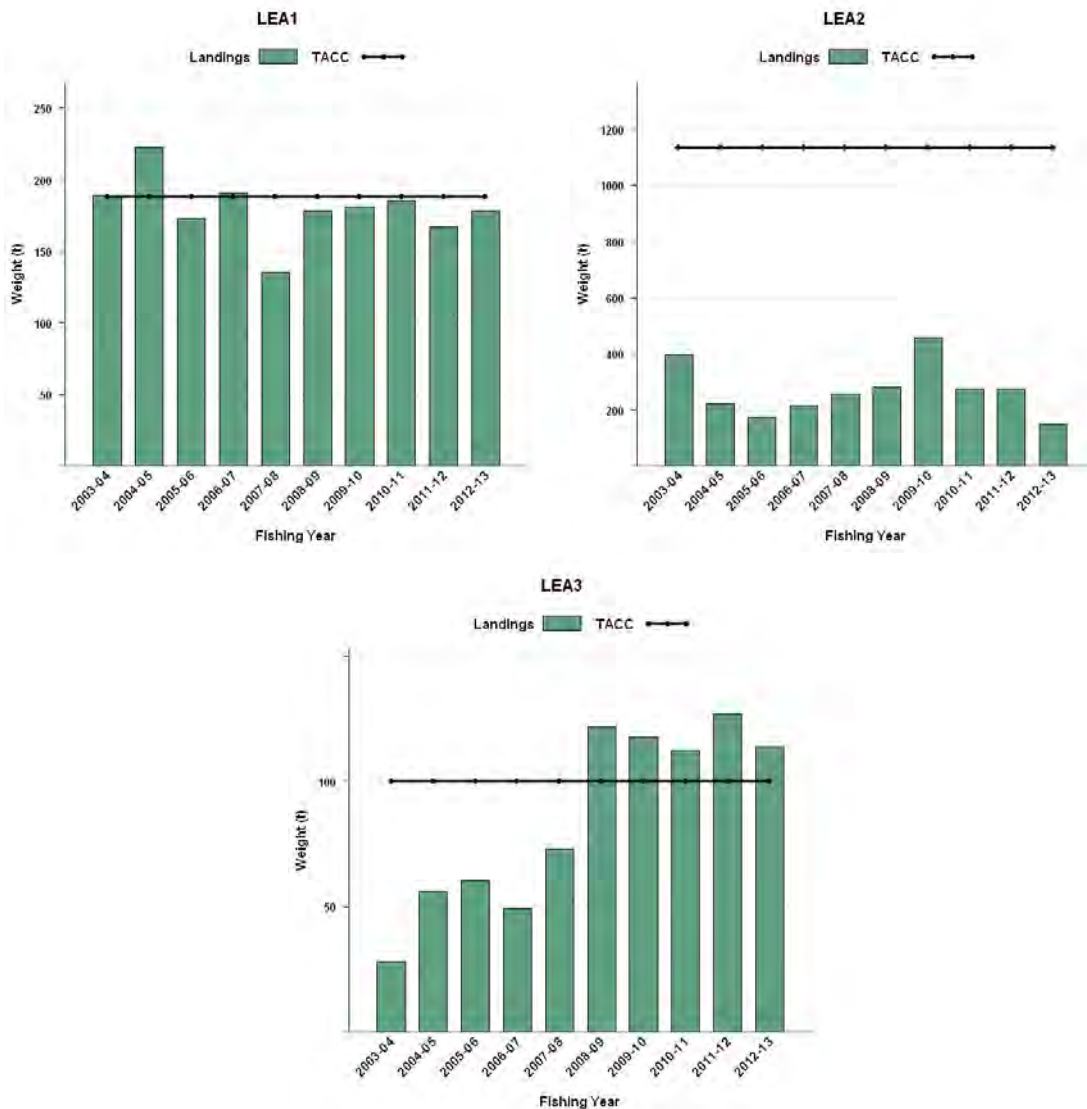

Figure 1: Historical landings and TACCs for the main LEA stocks. From top left: LEA 1 (Auckland), LEA 2 (Central), and LEA 3 (South East).

1.3 Customary non-commercial fisheries

There is no quantitative information available to allow the estimation of the amount of leatherjacket taken by customary non-commercial fishers.

2. BIOLOGY

The New Zealand leatherjacket (*Meuschenia scaber*) is present around much of New Zealand, but is most common in the north. Trawl survey records show it to be widespread over the inner shelf north of East Cape and Cape Egmont, in the South Taranaki Bight, in Tasman and Golden Bays, Pegasus Bay and the South Canterbury Bight, extending to depths below 100 m, but with greatest abundance at 40–60 m (Anderson et al 1998). It was less commonly caught along the east coast of the North Island south of East Cape, off the northeast South Island (Cook Strait to Pegasus Bay), northwest South Island (Cape Farewell to Cape Foulwind), and around the South Otago and Southland coast. It has not been taken by trawl on the west coast south of Cape Foulwind.

The New Zealand leatherjacket also occurs in Australia, from New South Wales to the southern coast of West Australia. In the Australian southeast trawl fishery, *Meuschenia scaber* is the main leatherjacket species caught (Yearsley et al 1999). It was once believed that two similar species of leatherjacket occurred in New Zealand – ‘rough’ and ‘smooth’ – but these are now considered to be a single species with variable colouring. Kokiri is the Maori name, but is not in common usage. ‘Creamfish’ is a New Zealand trade name for the processed (headed/gutted/skinned) product, rather than a name for the fish itself.

Leatherjacket usually occur near reefs and over rough seafloor, but may be found over sand or some distance above the bottom. Although not a schooling species, it does occur in small groups.

There are no published studies on the age and growth *M. scaber*. According to Francis (1996, 2012) they live to at least seven years, maturing at two years and 19–22 cm. The males defend territories and eggs are laid within nests on the seafloor in spring and summer (Ayling & Cox 1982, Milicich 1986).

3. STOCKS AND AREAS

There have been no biological studies directly relevant to the recognition of separate stocks.

Figure 2: Leatherjacket biomass \pm 95% CI (estimated from survey CV's) and the time series mean (dotted line) estimated from the West Coast South Island trawl survey series.

LEATHERJACKET (LEA)

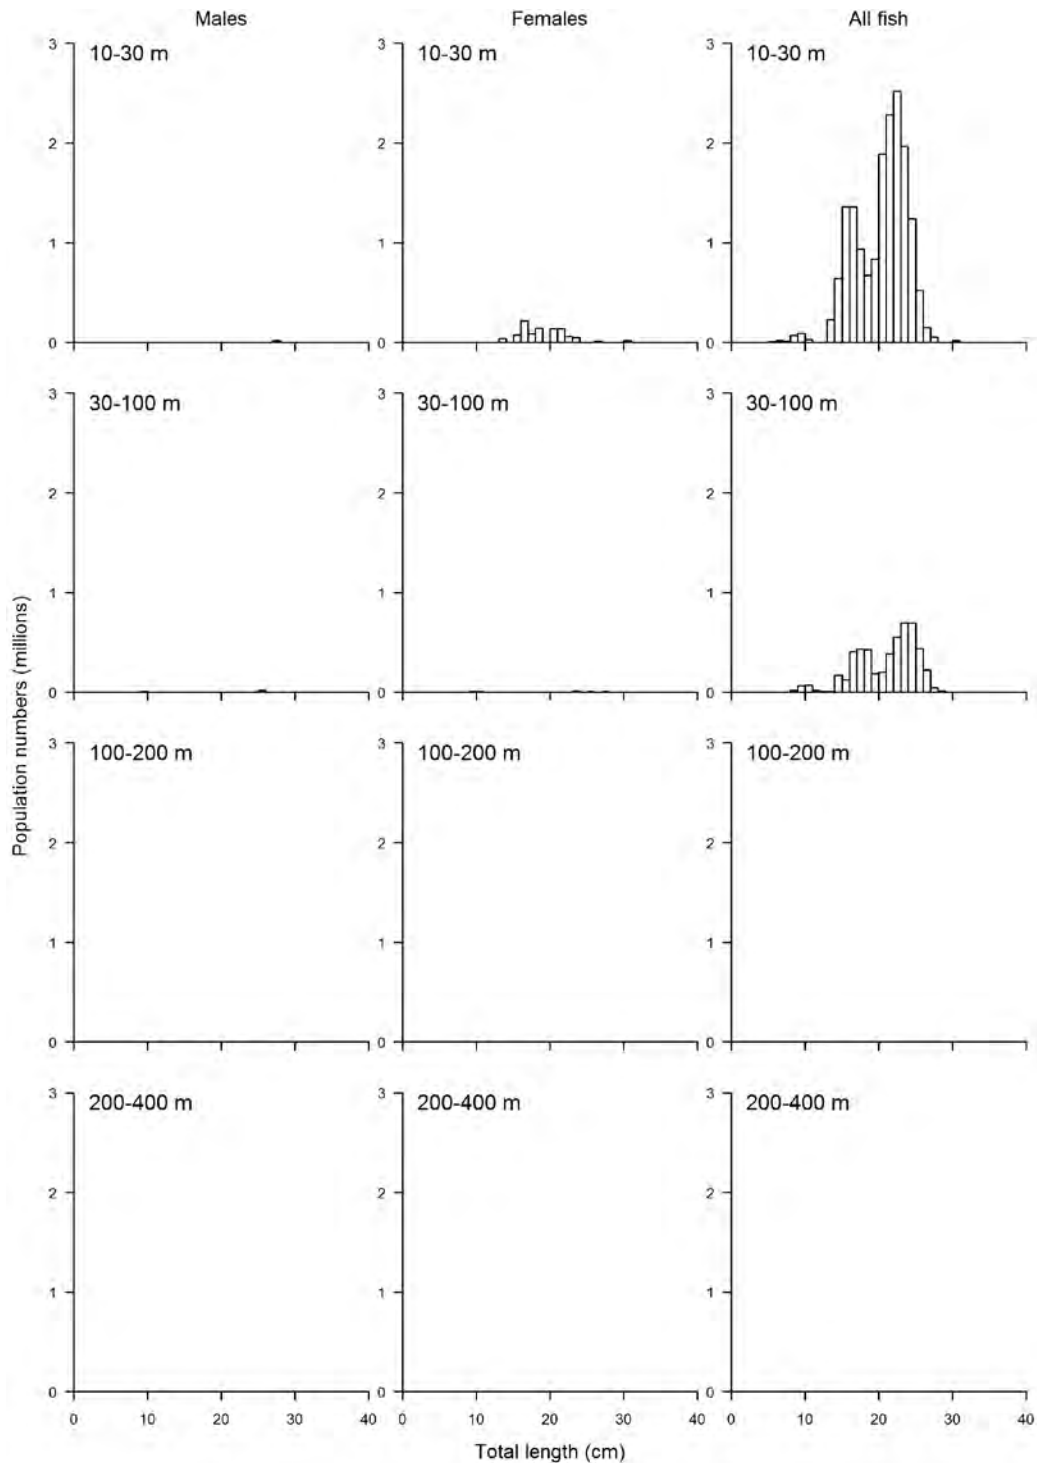

Figure 3: Scaled length frequency distributions for leatherjacket by depth range for all nine east coast South Island winter surveys combined. The 10–30 m depth range distribution includes data from only the last four surveys (2007, 2008, 2009, and 2012).

The West Coast South Island (WCSI) trawl survey probably monitors pre-recruit biomass of leatherjacket. The total biomass trends are shown in Figure 2.

The length distributions from the East Coast South Island trawl survey (Beentjes & MacGibbon 2013) show at least three clear modes at about 10 cm, 16 cm, and 23 cm (combined males, females, and unsexed). If they reach 20 cm after 1 year, as described by Ayling & Cox (1982), then the 16 cm mode represents the 0+ cohort turning 1 in August to November, and the 23 cm mode is comprised of multiple age classes (2 to 7 years). However, this explanation does not explain the presence of the smaller mode at 10 cm which seems more likely to be 0+ fish. The survey is therefore monitoring both pre-recruited cohorts, and fish in the recruited size range.

Plots of time series length frequency distributions (Figure 3) show that they were not caught in significant numbers until 2007 when the shallow strata were included in the surveys. Very few fish were sexed on any of the surveys. The two larger modes are consistently represented and overall the distributions show the presence of the pre-recruited cohorts, with 2012 having a larger proportion of recruited fish. The addition of the 10–30 m depth range has changed the shape of the distribution significantly and only the core plus shallow strata (10–400 m) time series that includes 2007 and 2012 is acceptable.

Biomass estimates in the core strata (30–400 m) are not valid given that so few fish were caught, and coefficients of variations are generally high ranging from 36 to 66% (mean = 55%). The additional biomass captured in the 10–30 m depth range accounted for 93% and 79% of the biomass in the core plus shallow strata (10–400 m) for 2007 and 2012 respectively, indicating that the core plus shallow strata (10–400 m) (Figure 4) is the only valid depth range within which to monitor leatherjacket biomass. The biomass in 2012 was marginally higher than that estimated in 2007.

4. STOCK ASSESSMENT

There has been no scientific assessment of the maximum sustainable yield, reference or current biomass of any of the leatherjacket stocks.

Figure 4: Leatherjacket biomass and 95% confidence intervals (total biomass only) estimated from the ECSI trawl survey core strata (30–400), and core plus shallow strata (10–400 m).

A characterisation and CPUE analysis for the LEA 3 fishery was undertaken by Langley (2013). Leatherjacket in LEA 3 are landed throughout the year, taken almost exclusively by bottom trawl gear in Statistical Areas 021–025 and 030 (Figure 5). Almost all of the LEA catch is taken in the 10–50 m depth range. The characterisation revealed that most of the increase in LEA 3 catch since 2005–06 is attributable to increased landings of leatherjacket catch from bottom trawls targeting spiny dogfish in Foveaux Strait (025).

A CPUE standardisation was undertaken using catch and effort data that included all trips that landed or targeted LEA 3, but did not include trips that did not catch LEA 3. Landed catch was assigned to effort records proportional to estimated catch, following the Starr (2007) methodology, with some refinements where the data were aggregated to CELR equivalent format (vessel/day/method/statistical area/target species) and then the records were defined as CELR equivalent. This method was

LEATHERJACKET (LEA)

somewhat problematic due to difference in the reliability of reporting of fishing location and target species between the CELR and TCER form types. The Foveaux Strait and Canterbury Bight fisheries were analysed separately. The Foveaux Strait analysis was rejected by the Working Group and is therefore not reported further.

The Canterbury Bight analysis was limited to the bottom trawl (BT) fishery in Statistical Areas 020 and 022, targeting a range of target species (RCO, BAR, FLA, ELE, TAR, WAR and GUR). The dataset included trips where 1 kg or more of LEA 3 were landed. The analysis had large numbers of very small catches. Eight vessels accounted for 80% of the catch. The working group requested that the Canterbury Bight delta lognormal model targeting FLA, ELE, GUR from 2002 (Target FLA, GUR, ELE post QMS) be used as these are the years when the reporting is likely to be more reliable. There was an indication that CPUE from the Canterbury Bight fishery has increased since the early 2000s, and these indices were robust to some key assumptions. The index (Figure 6) showed that the CPUE remained low at the start of the series and then began to increase from 2007–08 to 2011–12. However, some concerns were raised about the low number of vessels in the analysis and the development of new markets for this species that may have increased targeting or retention of this species in recent years, suggesting that the index may not be reliable as an index of abundance.

The Working Group concluded that this analysis only pertains to the stock unit for the East Coast of the South Island; is the best available information on the stock abundance at this stage but trawl survey data may provide better information in the medium and long-term; and that this is a Level 2 assessment and should be given a medium or mixed (2) overall assessment quality rank.

Figure 5: Distribution of reported catch for bottom trawl by Statistical Area in LEA 3 and fishing year from trips which landed leatherjacket in LEA 3 (Langley 2013).

Figure 6: A comparison of three standardised CPUE indices for leatherjacket on the East Coast South Island Langley (2013).

5. STATUS OF THE STOCK

Stock Structure Assumptions

Stock structure is unknown but for management purposes the QMA boundaries are assumed to represent the stock boundaries for this species. There are two distinct areas of catch distribution within LEA 3 (Foveaux Strait and East Coast South Island) and these may represent distinct biological stocks.

LEA 3 (East Coast South Island only)

Stock Status	
Year of Most Recent Assessment	2013
Assessment Runs Presented	CPUE: Target FLA, GUR, ELE post QMS
Reference Points	Target: 40% B_0 Soft Limit: 20% B_0 Hard Limit: 10% B_0 Overfishing threshold: F_{MSY}
Status in relation to Target	Unknown
Status in relation to Limits	Soft Limit: Unknown Hard Limit: Unlikely (< 40%)
Status in relation to Overfishing	It is Unknown whether overfishing is occurring

LEATHERJACKET (LEA)

Historical Stock Status Trajectory and Current Status

The 2013 standardised CPUE index for leatherjacket on the East Coast South Island.

Biomass and 95% confidence intervals (total biomass only) for leatherjacket caught by the ECSI trawl survey core strata (30–400), and core plus shallow strata (10–400 m).

Fishery and Stock Trends

Recent Trend in Biomass or Proxy	CPUE remained low at the start of the series (2002) and then began to increase from 2007–08 to 2011–12. The biomass index from the East Coast South Island trawl survey 30–400m strata has increased since 2008.
Recent Trend in Fishing Intensity or Proxy	Unknown because new markets for this species may have increased targeting or retention in recent years.
Other Abundance Indices	-
Trends in Other Relevant Indicators or Variables	-

Projections and Prognosis

Stock Projections or Prognosis	Unknown
Probability of Current Catch or TACC causing Biomass to	Soft Limit: Unknown Hard Limit: Unknown

Assessment Methodology and Evaluation		
Assessment Type	Level 2 - Partial Quantitative Stock Assessment	
Assessment Method	Standardised CPUE	
Assessment Dates	Latest assessment: 2013	Next assessment: 2015
Overall assessment quality rank	2 - Medium or Mixed Quality: CPUE may be compromised by the low number of vessels in the analysis and trends in targeting or retention of leatherjacket; the trawl survey has only covered the entire habitat since 2007.	
Main data inputs (rank)	- catch and effort data from bottom trawl sets targeting FLA, GUR and ELE - trawl survey biomass index	2 - Medium or mixed quality 2 - Medium or mixed quality
Data not used (rank)	Foveaux Strait CPUE index The trawl survey biomass estimates from the 10–400m strata.	3 – Low Quality: based on only a single vessel that has recently started targeting LEA. 3 – Low Quality: confidence intervals large and only two data points
Changes to Model Structure and Assumptions	New model	

remain below or to decline below Limits	
Probability of Current Catch or TACC causing Overfishing to continue or to commence	Unknown

Major Sources of Uncertainty	The low number of vessels in the analysis and new markets for this species may have increased targeting or retention in recent years. Trends in CPUE may therefore be a result of changes in reporting and retention rather than abundance. Total trawl survey biomass estimates for the entire survey area (10–400m) have large confidence intervals.
------------------------------	---

Qualifying Comments	-
----------------------------	---

Fishery Interactions
Leatherjacket are landed in fisheries targeting RCO, BAR, FLA, ELE, TAR, WAR and GUR, but are most commonly caught in FLA, GUR and ELE target bottom trawl sets. Some concerns have been raised about catch being taken in “hay paddocks”; these are polychaete worm beds that are biologically sensitive, habitat forming areas, which appear to be diminishing in areal extent as a consequence of disturbance from bottom trawling.

Research Needs
Fishery characterisations that include interviews with fishers and processors are required to assess the degree to which changes in fishing practices and economic drivers may have influenced CPUE trends. Trawl surveys need to continue to include the shallow strata in order to monitor the abundance of leatherjacket on the east coast of the South Island.

LEATHERJACKET (LEA)

Reported landings and TACCs by Fishstock for the 2012–13 fishing year are summarised in Table 3.

Table 3: Summary of TACCs (t) and reported landings (t) of leatherjacket for the most recent fishing year.

Fishstock		FMA	2012–13 Actual TACC	2012–13 Reported landings
LEA 1	Auckland (East) (West)	1, &9	188	178
LEA 2	Central (East) (West), Challenger	2,7&8	1 136	150
LEA 3	South east (coast), Southland, Sub-Antarctic	3, 4, 5 & 6	100	114
LEA 4	South east (Chatham)		7	0
Total			1 431	442

LING

(Genypterus blacodes)

Hoka

1. FISHERY SUMMARY

1.1 Commercial fisheries

Ling was introduced into the Quota Management System (QMS) on 1 October 1986. Ling are widely distributed through the middle depths (200–800 m) of the New Zealand EEZ, particularly to the south of latitude 40° S. From 1975 to 1980 there was a substantial longline fishery on the Chatham Rise (and to a lesser extent in other areas), carried out by Japanese and Korean longliners. Since 1980 ling have been caught by large trawlers, both domestic and foreign owned, and by small domestic longliners and trawlers. In the early 1990s the domestic fleet was increased by the addition of several larger longliners fitted with autoline equipment. This caused a large increase in the catches of ling off the east and south of the South Island (LIN 3, 4, 5 and 6). However, since about 2000 there has been a declining trend in catches taken by line vessels in most areas, offset, to some extent, by increased trawl landings.

The principal grounds for smaller domestic vessels are the west coast of the South Island (WCSI) and the east coast of both main islands south of East Cape. For the large trawlers the main sources of ling are Puysegur Bank and the slope of the Stewart-Snares shelf and waters in the Auckland Islands area. Longliners fish mainly in LIN 3, 4, 5 and 6. In 2011–12, landings from Fishstocks LIN 2, LIN 3, LIN 4 and LIN 6 were significantly under-caught relative to their TACCs by 49%, 37%, 45% and 76%, respectively. The LIN 5 and LIN 7 TACCs were slightly over-caught (by 2% and 10%, respectively). Reported landings by nation from 1975 to 1987–88 are shown in Table 1, and reported landings by Fishstock from 1983–84 to 2011–12 are shown in Table 2. Figure 1 shows the historical landings and TACC values for the main LIN stocks.

Under the Adaptive Management Programme (AMP), the TACC for LIN 1 was increased to 400 t from 1 October 2002, within an overall TAC of 463 t. All stocks including LIN 1 were removed from the AMP on 30th September 2009. In an earlier proposal for the 1994–95 fishing year, TACCs for LIN 3 and 4 had been increased to 2810 and 5720 t, respectively. These stocks were removed from the AMP from 1 October 1998, with TACCs maintained at the increased level. However, from 1 October 2000, the TACCs for LIN 3 and 4 were reduced to 2060 and 4200 t, respectively. From 1 October 2004, the TACCs for LIN 5 and LIN 6 were increased by about 20% to 3595 t and 8505 t, respectively. From 1 October 2009, the TACC for LIN 7 was increased from 2225 t to 2474 t. All other TACC increases since 1986–87 in all stocks are the result of quota appeals.

LING (LIN)

Table 1: Reported landings (t) from 1975 to 1987–88. Data from 1975 to 1983 from MAF; data from 1983–84 to 1985–86 from FSU; data from 1986–87 to 1987–88 from QMS. –, no data available.

* Reported by calendar year

Reported April 1 to March 31 (except domestic vessels, which reported by calendar year).

† Reported April 1 to Sept 30 (except domestic vessels, which reported by calendar year).

§ Reported Oct 1 to Sept 30.

Figure 1: Historical landings and TACC for the seven main LIN stocks. From top to bottom: LIN 1 (Auckland East) and LIN 2 (Central East). Note that these figures do not show data prior to entry into the QMS.

Figure 1 (continued): Historical landings and TACC for the seven main LIN stocks. From top to bottom: LIN 3 (South East Coast), LIN 4 (South East Chatham Rise) and LIN 5 (Southland). Note that these figures do not show data prior to entry into the QMS.

Figure 1 (continued): Historical landings and TACC for the seven main LIN stocks. From top to bottom: LIN 6 (Sub-Antarctic), and LIN 7 (Challenger). Note that these figures do not show data prior to entry into the QMS.

1.2 Recreational fisheries

The 1993–94 North region recreational fishing survey (Bradford 1996) estimated the annual recreational catch from LIN 1 as 10 000 fish (CV 0.23). With a mean weight likely to be in the range of 1.5 to 4 kg, this equates to a harvest of 15–40 t.

Recreational catch was recorded from LIN 1, 5, and 7 in the 1996 national diary survey. The estimated harvests (LIN 1, 3000 fish; LIN 5, less than 500; LIN 7, less than 500) were too low to provide reliable estimates.

1.3 Customary non-commercial fisheries

Quantitative information on the level of Maori customary non-commercial take is not available. Ling bones have been recovered from archaic middens throughout the South Island and southern North Island, and on Chatham Island (Leach & Boocock 1993). In South and Chatham Islands, ling comprised about 4% (by number) of recovered fish remains.

1.4 Illegal catch

It is believed that up to the mid 1990s some ling bycatch from the west coast hoki fishery was not reported. Estimates of total catch including non-reported catch are given in Table 2 for LIN 7. It is believed that in recent years, some catch from LIN 7 has been reported against other ling stocks

(probably LIN 3, 5, and 6). The likely levels of misreporting are moderate, being about 250–400 t in each year from 1989–90 to 1991–92 (Dunn 2003).

1.5 Other sources of mortality

The extent of any other sources of mortality is unknown.

Table 2: Reported landings (t) of ling by Fishstock from 1983–84 to 2012–13 and actual TACCs (t) from 1986–87 to 2012–13. Estimated landings for LIN 7 from 1987–88 to 1992–93 include an adjustment for ling bycatch of hoki trawlers, based on records from vessels carrying observers. QMS data from 1986-present.

* FSU data.

§ Includes landings from unknown areas before 1986–87, and areas outside the EEZ since 1995–96.

2. BIOLOGY

Ling live to a maximum age of about 30 years; fewer than 0.2% of successfully aged ling have been older than 30 years. A growth study of ling from five areas (west coast South Island, Chatham Rise, Bounty Plateau, Campbell Plateau, Cook Strait) showed that females grew significantly faster and reached a greater size than males in all areas, and that growth rates were significantly different between areas. Ling grow fastest in Cook Strait and slowest on the Campbell Plateau (Horn 2005).

M was initially estimated from the equation $M = \log_e 100/\text{maximum age}$, where maximum age is the age to which 1% of the population survives in an unexploited stock. The mean M calculated from five samples of age data was 0.18 (range = 0.17–0.20). However, a recent review of M , and results of modelling conducted in 2007, suggests that this parameter may vary between stocks (Horn 2008b). The M for Chatham Rise ling appears to be lower than 0.18, while for Cook Strait and west coast South Island the value is probably higher than 0.18.

Ling in spawning condition have been reported in a number of localities throughout the EEZ (Horn 2005). Time of spawning appears to vary between areas: July to November on the Chatham Rise; September to December on Campbell Plateau and Puysegur Bank; September to February on the Bounty Plateau; July to September off west coast South Island and in Cook Strait. Little is known about the distribution of juveniles until they are about 40 cm total length, when they begin to appear in trawl samples over most of the adult range.

Ling appear to be mainly bottom dwellers, feeding on crustaceans such as *Munida* and scampi and also on fish, with commercial fishing discards being a significant dietary component (Dunn et al. 2010). However, they may at times be caught well above the bottom, for example when feeding on hoki during the hoki spawning season.

Biological parameters relevant to the stock assessment are shown in Table 3.

Table 3: Estimates of biological parameters from Horn (2005). See Section 3 for definitions of Fishstocks.

3. STOCKS AND AREAS

A review of ling stock structure (Horn 2005) examined diverse information from studies of morphometrics, genetics, growth, population age structures, and reproductive biology and behavior, and indicated that there are at least five ling stocks, i.e., west coast South Island, Chatham Rise, Cook Strait, Bounty Plateau, and the Southern Plateau (including the Stewart-Snares shelf and Puysegur Bank). Stock affinities of ling north of Cook Strait are unknown, but spawning is known to occur off Northland, Cape Kidnappers, and in the Bay of Plenty.

4. STOCK ASSESSMENT

An updated CPUE analysis for the ling target bottom longline fishery was conducted in 2014. An analysis of CPUE for LIN 2 was last conducted in 2003 (Horn, 2004). The stock assessments for two ling stocks (LIN 7WC, west coast South Island; LIN 7CK, Cook Strait) were updated in 2013. Assessments for other stocks were updated in 2007 (LIN 6B, Bounty Plateau), or 2012 (LIN 3&4, Chatham Rise; LIN 5&6, Sub-Antarctic). All assessments were updated using a Bayesian stock model implemented using the general-purpose stock assessment program CASAL (Bull et al 2012).

4.1 Estimates of fishery parameters and abundance

Catch histories by stock and fishery are presented in Table 4, and other model input parameters are shown in Table 5. Estimates of relative abundance from standardised CPUE analyses (Table 6) and trawl surveys (Table 7) are also presented below.

Table 4: Estimated catch histories (t) for LIN 2[†] (ECNI), LIN 3&4 (Chatham Rise), LIN 5&6 (Campbell Plateau), LIN 6B (Bounty Platform), LIN 7WC (WCSI section of LIN 7), and LIN 7CK (Cook Strait). Landings have been separated by fishing method (trawl or line), and, for the LIN 5&6 line fishery, by pre-spawning (Pre) and spawning (Spn) season.

4.2 East Coast North Island, (LIN 2, statistical areas 11–15)

In 2014 a catch-per-unit-effort (CPUE) analysis was conducted on data from the LIN 2 fishery. Estimated catch data and effort data from bottom longliners that fished in FMA 2 statistical areas 11-15 (ECNI) targeting ling where there was a positive catch were used. The estimated catch and effort data were rolled up by vessel/day/ statistical area after a filter was applied to individual fishing events to retain estimated catch from the top five species together with all effort.

A GLM model (model 1) was fitted using a core vessel fleet where individual vessels had to have fished for four or more years in the fishery, had fished a minimum of 10 days per year. One auto-longlining vessel was excluded because it was an outlier in terms of numbers of hooks set, and created patterns in the residuals.

The sensitivity of the CPUE time series was tested for a range of alternative sets of input data: vessels using very large numbers of hooks per day (>10 000) were either included or excluded; changes in fishing power and fleet were minimized by fitting only the most recent time series (2000-2013); data from statistical area 16 (Cook Strait) were either included or excluded; and fitting was carried out with/without the use of interaction terms. An all-target model using bottom longline data that targeted or caught ling was also developed with 'target species' included as an explanatory variable. The GLM trend was robust to all sensitivities investigated.

The standardized CPUE index for ling from the ECNI demonstrates an initial decline consistent with the previous assessment (Horn 2004), followed by a period of stability (2002–2010) with lower CPUE in 2011–12 and 2012–13 (Figure 2). This pattern was consistent across all GLM scenarios examined.

Figure 2. Estimated ling catch (bars) and standardized CPUE indices. Blue line and triangles from Horn (2004) and the 2014 updated index (red line and circles) for ECNI statistical areas 11-15 for core bottom longline vessels targeting ling. The two CPUE series were normalized to the overlapping fishing years (1992-2001).

Chatham Rise, LIN 3 & LIN 4

LIN 3

4.3 Chatham Rise, LIN 3 & LIN 4

4.3.1 Biomass estimates

Biomass in the core strata (30–400 m) for the east coast South Island trawl survey is consistently lower in recent surveys compared to that in the 1990s (Figure 3). Coefficients of variation are also variable ranging from 17 to 35%, (mean 23%) and overall can be regarded as low. The additional biomass in the 10–30 m depth range is negligible.

Figure 3: Ling total biomass and 95% confidence intervals for the all ECSI winter surveys in core strata (30–400 m), and core plus shallow strata (10–400 m) in 2007 and 2012.

4.3.2 Length frequency distributions

The length distributions for the east coast South Island trawl survey show two distinct modes, particularly in the shallower depths, centred at about 50 cm and 90 cm (combined males, females, and unsexed) (Figure 4). Both modes will comprise multiple year classes. Plots of time series length frequency distributions are generally consistent among surveys with indications of fewer larger fish (mode around 90 cm) in recent years. The addition of the 10–30 m depth range has not changed the shape of the length frequency distribution.

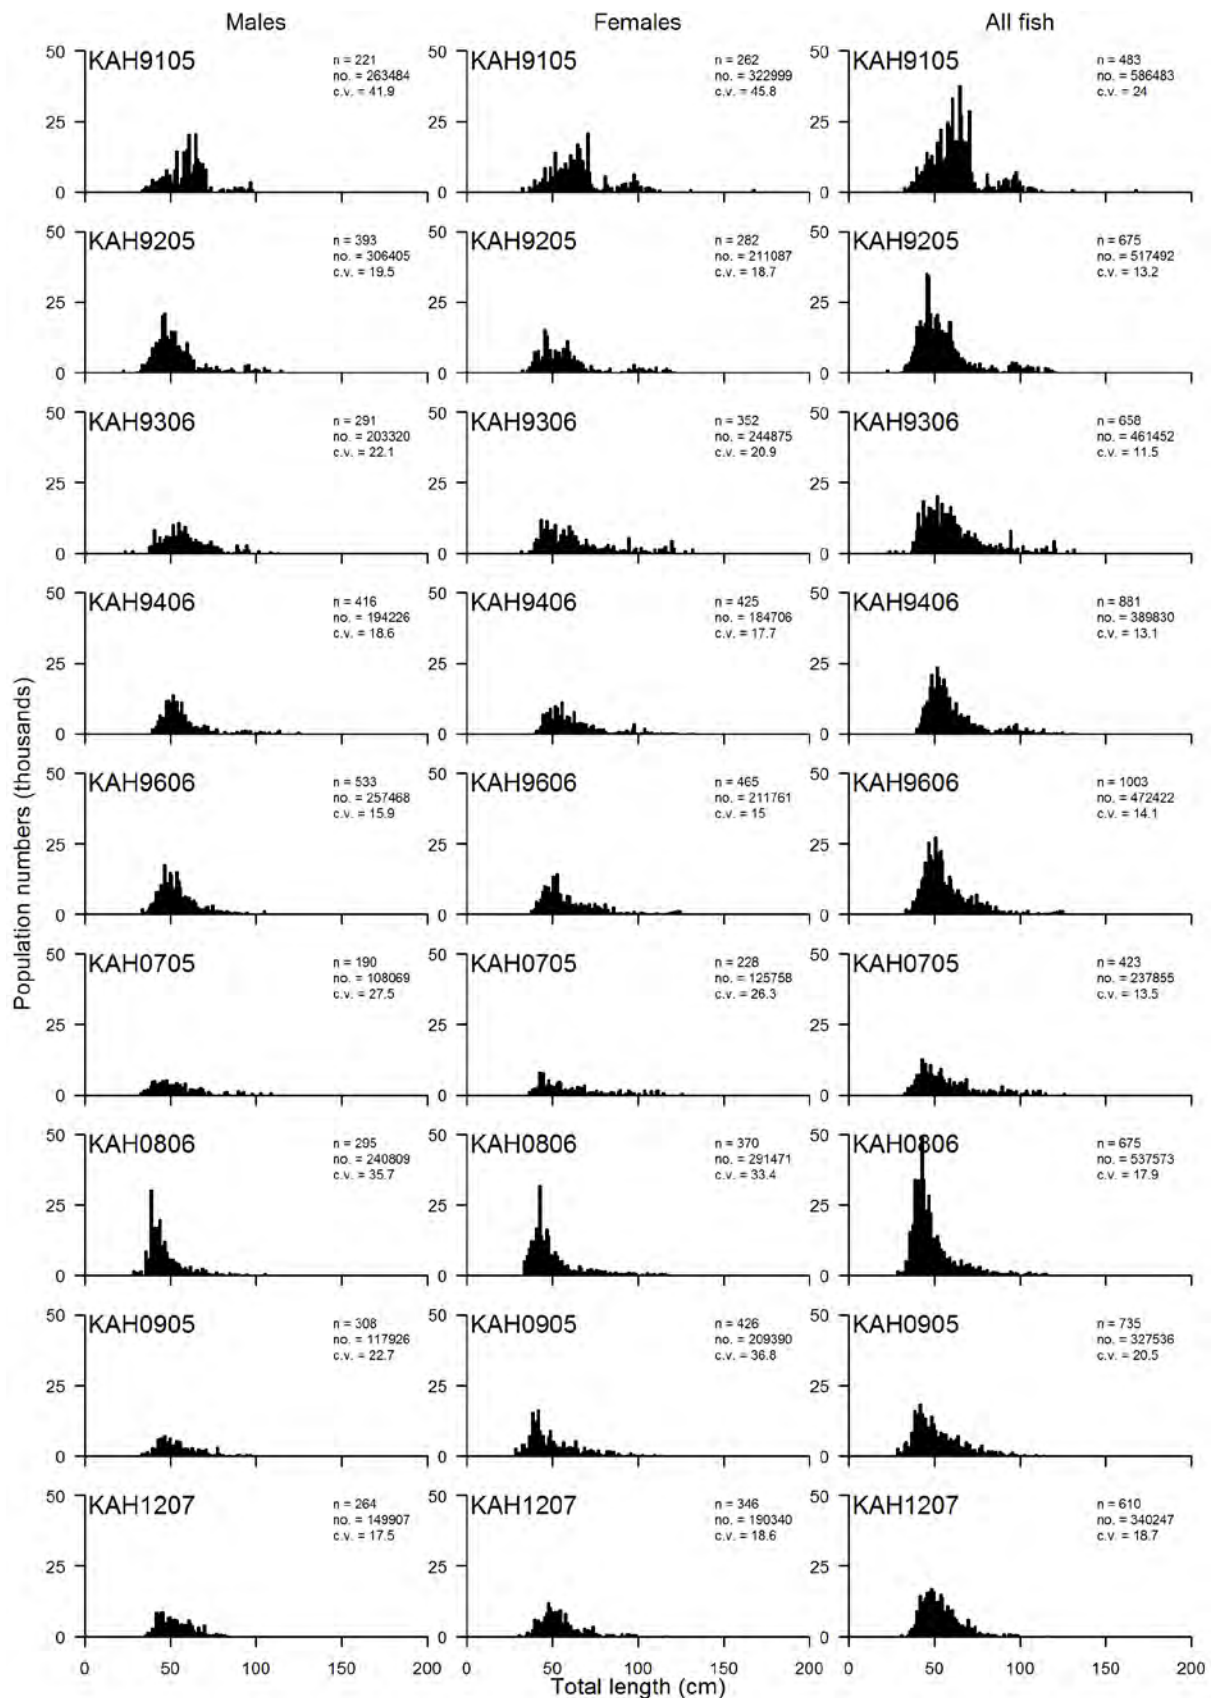

Figure 4: Scaled length frequency distributions for ling in core strata (30–400 m) for all nine ECSI winter surveys. Population estimates are for the core strata only. n, number of fish measured; no., population number; c.v., coefficient of variation.

4.3.3 Model structure and inputs

The stock assessment for LIN 3&4 (Chatham Rise) was updated in 2012. For final model runs, the full posterior distribution was sampled using Markov Chain Monte Carlo (MCMC) methods, based on the Metropolis-Hastings algorithm. Bounded estimates of spawning stock virgin (B_0) and current (B_{2011}) biomass were obtained. Year class strengths and fishing selectivity ogives were estimated in the model. Trawl fishery and research survey selectivity ogives were fitted as double normal curves; line fishery ogives were fitted as logistic curves. MCMC chains were constructed using a burn-in length of 5×10^5 iterations, with every 1000th sample taken from the next 10^6 iterations (i.e., a final sample of length 1000 was taken from the Bayesian posterior).

For LIN 3&4, model input data included catch histories, biomass and sexed catch-at-age data from a summer trawl survey series, sexed catch-at-age from the trawl fishery, line fishery CPUE, unsexed catch-at-age and catch-at-length from the line fishery, and estimates of biological parameters. The catch history, biological input parameters, and estimates of relative abundance used in the model are shown in Tables 4–7. The stock assessment model partitioned the population into two sexes, and age groups 3 to 25 with a plus group. The model's annual cycle is described in Table 8.

Table 8: LIN 3&4 — Annual cycle of the stock model, showing the processes taking place at each time step, their sequence within each time step, and the available observations. Fishing and natural mortality that occur within a time step occur after all other processes, with half of the natural mortality for that time step occurring before and half after the fishing mortality.

Step	Period	Processes	M^1	Age ²	Description	Observations
						%Z ³
1	Dec–Aug	Recruitment fisheries (line & trawl)	0.9	0.5	Trawl survey (summer) Line CPUE Line catch-at-age/length Trawl catch-at-age	0.2 0.5
2	Sep–Nov	Spawning and increment ages	0.1	0	–	

^{1.} M is the proportion of natural mortality that was assumed to have occurred in that time step.

^{2.} Age is the age fraction, used for determining length-at-age, that was assumed to occur by the start of that time step.

^{3.} %Z is the percentage of the total mortality in the step that was assumed to have taken place at the time each observation was made.

Most priors were intended to be uninformed, and were specified with wide bounds. The exception was an informative prior for the trawl survey q . The prior on q for all the *Tangaroa* trawl surveys was estimated assuming that the catchability constant was a product of areal availability (0.5–1.0), vertical availability (0.5–1.0), and vulnerability between the trawl doors (0.03–0.40). The resulting (approximately lognormal) distribution had mean 0.13 and CV 0.70, with bounds assumed to be 0.02 to 0.30. Penalty functions were used to constrain the model so that any combination of parameters that did not allow the historical catch to be taken was strongly penalised. A penalty was applied to the estimates of year class strengths to encourage estimates that averaged to 1.

Investigative model runs identified a conflict between the line fishery CPUE and the trawl survey biomass index, where the line fishery biomass index declined between 1991 and 1997, but the trawl survey index remained relatively flat throughout. This difference could not be resolved in a single model run by assuming different selectivity ogives for each biomass index. Therefore, to remove this conflict, a base case model run (Base) used all the observational data except those from the line fishery; the trawl survey biomass index being preferred in the base case because these data were fishery independent. A sensitivity run (NoTrawl) then included the line fishery data, and excluded the trawl survey data.

The error distributions assumed were multinomial for the at-age and at-length data, and lognormal for all other data. The weight assigned to each data set was controlled by the error coefficient of variation (CV). The observation-error CVs were calculated using standard formulae. An additional process error CV of 0.2 was added to the trawl survey biomass index following Francis et al (2001), and a process error CV for the line fishery CPUE was estimated at 0.15 following Francis (2011). The multinomial observation error CVs for the at-age and at-length data were then adjusted using the reweighting procedure of Francis (2011). Reweighting of the at-age and at-length data was completed for the base and sensitivity runs separately.

4.3.4 Model estimates

The fits to the biomass indices, catch-at-age and catch-at-length data, were reasonable to good in all model runs, with generally balanced residuals. Posterior distributions of year class strength estimates from the base case model run are shown in Figure 5; the distribution from the NoTrawl run differed little from the base case. Since 1980, year class strengths were below average except for a period between 1994 and 1999, and in 2007. Estimated year class strengths were not widely variable, with all medians being between 0.5 and 2. Ling were first caught by the trawl survey (mean selectivity A_{50} of 5.2 years), then the trawl fishery (mean A_{50} of 8.0 years), and then the line fishery (A_{50} of 11.0 years). Males were estimated to be less vulnerable than females to the trawl and line fisheries. The estimated median M was 0.15.

The assessment is driven by the catch history, and by catch-at-age data, which contain information indicative of a stock decline during the 1990s. This is supported by a declining trend in the line fishery CPUE index during that time.

Figure 5: LIN 3&4 — Estimated posterior distributions of year class strength for the base model. The horizontal line indicates a year class strength of one. Individual distributions show the marginal posterior distribution, with horizontal lines indicating the median.

Although estimates of current and virgin stock size were imprecise, it was unlikely that B_0 was lower than 110 000 t for this stock, and very likely that biomass in 2011 was greater than 44% of B_0 (Table 9, Figure 6).

Table 9: LIN 3&4 — Bayesian median and 95% credible intervals (in parentheses) of B_0 and B_{2011} (in tonnes), and B_{2011} as a percentage of B_0 for both model runs.

Model run	B_0		B_{2011}		$B_{2011}(\%B_0)$	
Base	127 400	(110 400–170 300)	70 800	(48 600–121 900)	55	(44–71)

Figure 6: LIN 3&4 — Estimated posterior distributions of the biomass trajectory (in tonnes) from the base run. Broken lines show the 95% credible intervals and the solid line the median.

The model indicated an increasing biomass since 2004 (driven by a reduction in catch) (Figure 6). Annual landings from the LIN 3&4 stock have been less than 4600 t since 2004, markedly lower than the 6000–8000 t taken annually between 1992 and 2003. Biomass projections derived from this assessment are shown below (Section 4.9).

4.4 Sub-Antarctic, LIN 5 & LIN 6 (excluding Bounty Plateau)

4.4.1 Model structure and inputs

The stock assessment for LIN 5&6 (Sub-Antarctic) was updated in 2012. For final runs, the full posterior distribution was sampled using Markov Chain Monte Carlo (MCMC) methods, based on the Metropolis-Hastings algorithm. Bounded estimates of spawning stock virgin (B_0) and current (B_{2011}) biomass were obtained. Year class strengths and fishing selectivity ogives were also estimated in the model. Trawl fishery selectivity ogives were fitted as double normal curves; line fishery and research survey ogives were fitted as logistic curves. Selectivities were assumed constant over all years in each fishery/survey.

MCMC chains were constructed using a burn-in length of 5×10^5 iterations, with every 2500th sample taken from the next 2.5×10^6 iterations (i.e., a final sample of length 1000 was taken from the Bayesian posterior).

For LIN 5&6, model input data include catch histories, biomass and catch-at-age data from summer and autumn trawl survey series, two line fishery CPUE series (from the spawning and home ground fisheries), catch-at-age from the spawning ground and home ground line fisheries, catch-at-age data from the trawl fishery, and estimates of biological parameters. A base case model run that incorporated all the data except the CPUE series is presented, with a sensitivity run that included the CPUE series. The stock assessment model partitions the population into two sexes, and age groups 3 to 25 with a plus group. The model's annual cycle is described in Table 10.

Table 10: LIN 5&6 — Annual cycle of the stock model, showing the processes taking place at each time step, their sequence within each time step, and the available observations. Fishing and natural mortality that occur within a time step occur after all other processes, with half of the natural mortality for that time step occurring before and half after the fishing mortality.

Step	Period	Processes	M^1	Age ²	Description	Observations
						%Z ³
1	Dec–Aug	Recruitment Non-spawning fisheries (trawl & line)	0.75	0.4	Trawl survey (summer)	0.1
					Trawl survey (autumn)	0.5
					Line CPUE (non-spawn)	0.7
					Line (non-spawn) catch-at-age	
					Trawl catch-at-age	
2	Sep–Nov	Increment ages Spawning fishery (line)	0.25	0.0	Line CPUE (spawning)	0.5
					Line (spawning) catch-at-age	

^{1.} M is the proportion of natural mortality that was assumed to have occurred in that time step.

^{2.} Age is the age fraction, used for determining length-at-age, that was assumed to occur in that time step.

^{3.} %Z is the percentage of the total mortality in the step that was assumed to have taken place at the time each observation was made.

Lognormal errors, with known CVs, were assumed for all relative biomass, proportions-at-age, and proportions-at-length observations. The CVs available for those observations of relative abundance and catch data allow for sampling error only. However, additional variance, assumed to arise from differences between model simplifications and real world variation, was added to the sampling variance. The additional variance, termed process error, was estimated in MPD runs of the model (Table 11 and fixed in all subsequent runs).

The assumed prior distributions used in the assessment are given in Table 12. Most priors were intended to be relatively uninformed, and were specified with wide bounds. The exceptions were the choice of informative priors for the trawl survey q . The priors on q for all the *Tangaroa* trawl surveys were estimated assuming that the catchability constant was a product of areal availability (0.5–1.0), vertical availability (0.5–1.0), and vulnerability between the trawl doors (0.03–0.40). The resulting (approximately lognormal) distribution had mean 0.13 and CV 0.70, with bounds assumed to be 0.02 to 0.30.

Table 11: LIN 5&6 — Summary of the relative abundance series applied in the models, including source years (Years), and the estimated process error (CV) added to the observation error.

Data series	Years	Process error CV
Trawl survey proportion at age (<i>Amaltal Explorer</i> , Nov)	1990	0.15
Trawl survey biomass (<i>Tangaroa</i> , Nov–Dec)	1992–94, 2001–10	0.01
Trawl survey proportion at age (<i>Tangaroa</i> , Nov–Dec)	1992–94, 2001–10	0.15
Trawl survey biomass (<i>Tangaroa</i> , Mar–May)	1992–93, 1996, 1998	0.01
Trawl survey proportion at age (<i>Tangaroa</i> , Mar–May)	1992–93, 1996, 1998	0.01
CPUE (longline, spawning fishery)	1991–2010	0.18
CPUE (longline, non-spawning fishery)	1991–2010	0.18
Commercial longline proportion-at-age (spawning, Oct–Dec)	2000–08, 2010	0.3
Commercial longline proportion-at-age (non-spawn, Feb–Jul)	1999, 2001, 2003, 2005, 2009, 2010	0.3
Commercial trawl proportion-at-age (Sep–Apr)	1992–94, 1996, 1998, 2001–10	0.3

Table 12: LIN 5&6 — Assumed prior distributions and bounds for estimated parameters in the assessments. The parameters for lognormal priors are mean (in log space) and CV

Parameter description	Distribution	Parameters		Bounds	
		Mean	CV	Lower	Upper
B_0	Uniform-log	–	–	50 000	800 000
Year class strengths	Lognormal	1.0	0.70	0.01	100
Trawl survey q	Lognormal	0.13	0.70	0.02	0.3
CPUE q	Uniform-log	–	–	1e-8	1e-3
Selectivities	Uniform	–	–	0	20–200*
Process error CV	Uniform-log	–	–	0.001	2
$M(x_0, y_0, y_1, y_2)$	Uniform	–	–	3, 0.01, 0.01, 0.01	15, 0.6, 1.0, 1.0

* A range of maximum values were used for the upper bound

Penalty functions were used to constrain the model so that any combination of parameters that did not allow the historical catch to be taken was strongly penalised. A small penalty was applied to the estimates of year class strengths to encourage estimates that averaged to 1.

The catch history, biological input parameters, and estimates of relative abundance used in the model are shown in Tables 4–7.

4.4.2 Model estimates

Descriptions of two model runs reported are as follows.

- Base case — catch history, all relative abundance series listed in Tables 4, 6, and 7, M estimated as an ogive independent of sex, double-normal selectivity ogives for the trawl fishery, logistic ogives for the line fisheries and the resource survey series.
- CPUE — the base case model, but incorporating the two line fishery CPUE series.

Three other sensitivities were investigated: (1) splitting the summer survey series into early (1992–2006) and recent (2007–09) series with independent q s, (2) excluding the 2001 survey biomass point, and (3) fitting the survey ogives as double-normal. These models all produced estimates of stock status that were little different to those from the reported models.

Posterior distributions of year class strength estimates from the base case model run are shown in Figure 7; the distribution from the CPUE model run differed little from the base case. Year classes were generally weak from 1982 to 1992, strong from 1993 to 1996, and average since then (although 2005 may be strong). Overall, estimated year class strengths were not widely variable, with all medians being between 0.5 and 2. Consequently, biomass estimates for the stock declined through the 1990s, but have exhibited an upturn during the last 12 years (Figure 8). The biomass trajectory from the CPUE model was little different to that derived from the base case.

Biomass estimates for the stock appear very healthy, with estimated current biomass from the two reported models at about 89% of B_0 (Figure 8, Table 13). Annual exploitation rates (catch over vulnerable biomass) were low (less than 0.06) in all years as a consequence of the high estimated stock size in relationship to the level of relative catches.

Figure 7: LIN 5&6 — Estimated posterior distributions of year class strength from the base case run. The horizontal line indicates a year class strength of one. Individual distributions show the marginal posterior distribution, with horizontal lines indicating the median.

Figure 8: LIN 5&6 — Estimated median trajectories (with 95% credible intervals shown as dashed lines) for absolute biomass and biomass as a percentage of B_0 from the base case model run.

Table 13: LIN 5&6 — Bayesian median and 95% credible intervals (in parentheses) of B_0 and B_{2011} (in tonnes), and B_{2011} as a percentage of B_0 for both model runs.

Model run	B_0		B_{2011}		$B_{2011} (\%B_0)$	
Base case	395 660	(240 210–740 790)	355 190	(195 430–689 960)	89.2	(69.8–100.6)
CPUE	442 400	(258 010–763 190)	399 260	(214 270–703 600)	89.8	(74.1–100.3)

Resource survey and fishery selectivity ogives were relatively tightly defined. The survey ogive suggested that ling were fully selected by the research gear at about age 7–9. Fishing selectivities indicated that ling were fully selected by the trawl fishery at about age 9 years, and by the line fisheries at about age 12–16.

The assessment relied on biomass data from the Sub-Antarctic trawl survey series. The summer survey series was not particularly well fitted and had clear patterns in the residuals (Figure 9). It was also apparent that there can be marked changes in catchability between adjacent pairs of surveys. Estimated trawl survey catchability constants were moderately low (about 4–15% based on doorspread swept area estimates), but are consistent with the priors.

The assessments indicated a biomass trough about 1999, and some recovery since then. Although estimates of current and virgin stock size are very imprecise, it is most unlikely that B_0 was lower than 200 000 t for this stock, and it is very likely that current biomass is greater than 70% of B_0 . Probabilities that current and projected biomass will drop below selected management reference points are shown in Table 14.

Figure 9: LIN 5&6 — Observed relative biomass from the autumn (open squares) and summer (filled circles) Sub-Antarctic research trawl surveys. Survey biomass trajectories estimated in the base case model are also shown for the autumn (grey line) and summer (black line) surveys.

Table 14: LIN 5&6 — Probabilities that current (B_{2011}) and projected (B_{2016}) biomass will be less than 40%, 20% or 10% of B_0 . Projected biomass probabilities are presented for the base case model using two scenarios of future annual catch (i.e., 5900 t, and 12 100 t).

Biomass	Management reference points		
	40% B_0	20% B_0	10% B_0
B_{2011}	0.000	0.000	0.000
B_{2016} , 5900 t catch	0.000	0.000	0.000
B_{2016} , 12 100 t catch	0.000	0.000	0.000

Estimates of biomass projections derived from this assessment are shown below (Section 4.9).

4.5 Bounty Plateau, LIN 6B (Bounty Plateau only)

4.5.1 Model structure and inputs

The stock assessment for the Bounty Plateau stock (part of LIN 6) was updated in 2007. For final runs, the full posterior distribution was sampled using Markov Chain Monte Carlo (MCMC) methods, based on the Metropolis-Hastings algorithm. Bounded estimates of spawning stock virgin (B_0) and current (B_{2007}) biomass were obtained. Year class strengths and fishing selectivity ogives were also estimated in the model. Line fishery ogives were fitted as logistic curves.

MCMC chains were constructed using a burn-in length of 5×10^5 iterations, with every 1000th sample taken from the next 10^6 iterations (i.e., a final sample of length 1000 was taken from the Bayesian posterior).

For LIN 6B, model input data include catch histories, line fishery CPUE, catch-at-age and catch-at-length from the line fishery, and estimates of biological parameters. In the absence of sufficient stock-specific data, maturity ogives were assumed to be the same as for LIN 3&4, a stock with comparable growth parameters to LIN 6B. Only a base case model run is presented. The stock assessment model partitions the population into two sexes, and age groups 3 to 35 with a plus group. There is one fishery (longline) in the stock. The model's annual cycle is described in Table 15

Lognormal errors, with known CVs, were assumed for all relative biomass, proportions-at-age, and proportions-at-length observations. The CVs available for those observations of relative abundance and catch data allow for sampling error only. However, additional variance, assumed to arise from differences between model simplifications and real world variation, was added to the sampling variance. The additional variance, termed process error, was estimated in MPD runs of the model (Table 16) and fixed in all subsequent runs.

Table 15: LIN 6B — Annual cycle of the stock model, showing the processes taking place at each time step, their sequence within each time step, and the available observations. Fishing and natural mortality that occur within a time step occur after all other processes, with half of the natural mortality for that time step occurring before and half after the fishing mortality.

Step	Period	Processes	M^1	Age ²	Description	Observations
						%Z ³
1	Dec–Sep	recruitment fisher y (line)	0.9	0.5	Line CPUE	0.5
					Line catch-at-age/length	0.5
2	Oct–Nov	increment ages	0.1	0	–	

1. M is the proportion of natural mortality that was assumed to have occurred in that time step.
2. Age is the age fraction, used for determining length-at-age, that was assumed to occur in that time step.
3. %Z is the percentage of the total mortality in the step that was assumed to have taken place at the time each observation was made.

Table 16: LIN 6B — Summary of the relative abundance series applied in the models, including source years (Years), and the estimated process error (CV) added to the observation error.

Data series	Years	Process error CV
CPUE (longline, all year)	1992–2004	0.15
Commercial longline length-frequency (Nov–Feb)	1996, 2000–04	0.50
Commercial longline proportion-at-age (Dec–Feb)	2000–01, 2004	0.40

The assumed prior distributions used in the assessment are given in Table 17 All priors were intended to be relatively uninformed, and were estimated with wide bounds.

Table 17: LIN 6B — Assumed prior distributions and bounds for estimated parameters for the assessments. The parameters are mean (in log space) and CV for lognormal.

Parameter description	Distribution	Parameters		Bounds	
		Mean	CV	Lower	Upper
B_0	uniform-log	–	–	5000	100 000
Year class strengths	lognormal	1.0	0.7	0.01	100
CPUE q	uniform-log	–	–	1e-8	1e-3
Selectivities	uniform	–	–	0	20–200
Process error CV	uniform-log	–	–	0.001	2

* A range of maximum values were used for the upper bound

Penalty functions were used to constrain the model so that any combination of parameters that did not allow the historical catch to be taken was strongly penalised. A small penalty was applied to the estimates of year class strengths to encourage estimates that averaged to 1.

The catch history, biological input parameters, and estimates of relative abundance used in the model are shown in Tables 4–7.

4.5.2 Model estimates

Only a base case model run was completed.

Posterior distributions of year class strength estimates from the base case model run are shown in Figure 10.

Figure 10: LIN 6B — Estimated posterior distributions of year class strength from the base case run. The horizontal line indicates a year class strength of one. Individual distributions show the marginal posterior distribution, with horizontal lines indicating the median.

LING (LIN)

The assessment was driven largely by the catch-at-age and catch-at-length series from the line fishery; the first two years of CPUE data were not well fitted. Biomass estimates are listed in Table 18 and the biomass trajectory is shown in Figure 11. The assessment indicates a declining biomass throughout the history of the fishery. Estimates of current and virgin stock size are not well known, but current biomass is very likely to be above 50% of B_0 .

Table 18: LIN 6B — Bayesian median and 95% credible intervals (in parentheses) of B_0 and B_{2006} (in t), and B_{2006} as a percentage of B_0 for the base case model run.

Model run	B_0		B_{2006}		$B_{2006} (\%B_0)$
Base case	13 570	(10 850–19 030)	8 330	(4 860–14 730)	61 (45–79)

Figure 11: LIN 6B — Estimated posterior distributions of biomass trajectories as a percentage of B_0 , from the base case model run (including 5-year projections through to 2011 with assumed constant annual catch of 400 t). Distributions are the marginal posterior distribution, with horizontal lines indicating the median.

Biomass projections derived from this assessment are shown below (Section 4.9).

4.6 West Coast South Island, LIN 7WC

4.6.1 Model structure and inputs

The stock assessment for LIN 7WC (west coast South Island) was updated in 2013. The assessment model partitions the population into age groups 3 to 28 with a plus group, with no sex in the partition. The model's annual cycle is described in Table 19.

Table 19: LIN 7WC — Annual cycle of the stock model, showing the processes taking place at each time step, their sequence within each time step, and the available observations. Fishing and natural mortality that occur within a time step occur after all other processes, with half of the natural mortality for that time step occurring before and half after the fishing mortality.

Step	Period	Processes	M^1	Age ²	Observations	
					Description	%Z ³
1	Oct–May	Recruitment fishery (line)	0.75	0.5	Line catch-at-age	0.5
2	Jul–Sep	increment ages fishery (trawl)	0.25	0	Trawl survey biomass and catch at age Trawl catch-at-age Trawl CPUE	0.5

^{1.} M is the proportion of natural mortality that was assumed to have occurred in that time step.

^{2.} Age is the age fraction, used for determining length-at-age, that was assumed to occur in that time step.

^{3.} %Z is the percentage of the total mortality in the step that was assumed to have taken place at the time each observation was made.

The chosen base case was developed following the investigation of numerous previous models. It was found that the model could not reconcile some differences in sex ratios of the age-frequency data, so sex was removed from the partition.

Year class strengths and fishing selectivity ogives were also estimated in the model. Commercial trawl and research survey selectivities were fitted as double normal curves; the line fishery ogive was fitted as a logistic curve.

For final runs, the full posterior distribution was sampled using Markov Chain Monte Carlo (MCMC) methods, based on the Metropolis-Hastings algorithm. Bounded estimates of spawning stock virgin (B_0) and current (B_{2008}) biomass were obtained. MCMC chains were constructed using a burn-in length of 2×10^6 iterations, with every 4000th sample taken from the next 4×10^6 iterations (i.e., a final sample of length 1000 was taken from the Bayesian posterior). Single chain convergence tests were applied to resulting chains to determine evidence of non-convergence. No evidence of lack of convergence was found in the estimates of B_0 or $B_{current}/B_0$ from the base case model run.

For LIN 7WC, model input data include catch histories, trawl fishery CPUE, extensive catch-at-age data from the trawl fishery, sparse catch-at-age data from the line fishery, biomass estimates and proportion at age from comparable *Tangaroa* surveys in 2000 and 2012, and estimates of biological parameters (Table 20). A line fishery CPUE series was available, but was rejected as unlikely to be indexing stock abundance. The base case estimated instantaneous natural mortality, M , as a constant.

The error distributions assumed were multinomial for the proportions-at-age and lognormal for all other data. Biomass indices had assumed CVs set equal to the sampling CV, with additional process error of 0.2. The multinomial observation error effective sample sizes for the trawl fishery at-age data were adjusted using the reweighting procedure of Francis (2011). An *ad hoc* procedure was used for the at-age data from the line fishery and *Tangaroa* survey at-age data, giving the survey a relatively high weighting.

Table 20: LIN 7WC — Summary of the relative abundance series applied in the models, including source years (Years).

Data series	Years
CPUE (hoki trawl, Jun–Sep)	1987–2011
Commercial trawl proportion-at-age (Jun–Sep)	1991, 1994–2008
Commercial longline proportion-at-age	2003, 2012
Trawl survey biomass (<i>Tangaroa</i> , July)	2000, 2012
Trawl survey age data	2000, 2012

The assumed prior distributions used in the assessment are given in Table 21. Most priors were intended to be relatively uninformed, and were specified with wide bounds. The prior for the survey q was informative and was estimated using the Sub-Antarctic ling survey priors as a starting point (see Section 4.4.1) because the survey series in both areas used the same vessel and fishing gear. However, the WCSI survey area in the 200–650 m depth range in strata 0004 A–C and 0012 A–C comprised 6619 km²; seabed area in that depth range in the entire LIN 7 WC biological stock area (excluding the Challenger Plateau) is estimated to be about 20 100 km². So, because biomass from only 33% of the WCSI ling habitat was included in the indices, the Sub-Antarctic prior on μ was modified accordingly (i.e., $0.13 \times 0.33 = 0.043$), and the bounds were also reduced from [0.02, 0.30] to [0.01, 0.20]. The prior for M was informed and based on expert opinion. Priors for all selectivity parameters were assumed to be uniform.

Table 21: LIN 7WC — Assumed prior distributions and bounds for parameters estimated in the models. For lognormal distributions the figures are the logspace mean and the CV, and for normal distributions the figures are the mean and standard deviation .

Parameter description	Distribution	Parameters		Bounds	
B_0	uniform-log	–	–	10 000	500 000
Year class strengths	lognormal	1.0	0.7	0.01	100
<i>Tangaroa</i> survey q	lognormal	0.043	0.70	0.01	0.2
CPUE q	uniform-log	–	–	1e-8	1e-3
Selectivities	uniform	–	–	0	20–200*
M	normal	0.20	0.025	0.1	0.3

* A range of maximum values was used for the upper bound.

Penalty functions were used to constrain the model so that any combination of parameters that did not allow the historical catch to be taken was strongly penalised. A small penalty was applied to the estimates of year class strengths to encourage estimates that averaged to 1.

The catch history, biological input parameters, and estimates of relative abundance used in the model are shown in Tables 4–7.

4.6.2 Model estimates

MCMC runs of the base case and one sensitivity (where M was fixed at 0.18) were conducted.

Posterior distributions of year class strength estimates from the base case model run are shown in Figure 12. The YCS distribution from the sensitivity run was not visually different and is not shown.

Figure 12: LIN 7WC — Estimated posterior distributions of year class strength. The horizontal line indicates a year class strength of one. Individual distributions show the marginal posterior distribution, with horizontal lines indicating the median.

Both model runs were indicative of a B_0 greater than about 50 000 t (Table 22). The upper bound on B_0 is highly uncertain and dependent on the priors on the survey q and M . Both model runs also indicated a biomass decline from 2000–2012 (Figure 13). The model fit to the CPUE series was poor (Figure 14). Model estimates suggest a period of higher recruitment from 1978 to 1990 followed by lower recruitment since 1992. There was also some evidence for stronger recruitment in the most recent year for which an estimate can be made but this is highly uncertain (Figure 11).

Table 22: LIN 7WC — Bayesian median and 95% credible intervals (in parentheses) of B_0 and B_{2011} (in tonnes), and B_{2012} as a percentage of B_0 for all model runs. The base case estimates M .

Model run	B_0		B_{2011}		$B_{2012} (\%B_0)$	
Base case	99 200	(58 400–304 600)	70 350	(33 000–248 400)	71	(56–85)
$M = 0.18$	66 100	(50 300–142 900)	39 580	(23 600–109 200)	59	(46–79)

Figure 14: LIN 7WC —The fit of the base case model (MPD) to the commercial trawl CPUE index. The CPUE index has been scaled to the biomass using the estimated q .

4.7 Cook Strait, LIN 7CK

4.7.1 Model structure and inputs

A stock assessment of ling in Cook Strait (LIN 7CK) was completed in 2013. Because it is believed that the true M for the Cook Strait stock is higher than the ‘default’ value of 0.18, it was considered desirable to estimate M in the model, and so incorporate the effect of this uncertainty in M in the assessment. However, the simultaneous estimation of B_0 and M was not successful owing to the adoption of a multinomial likelihood (rather than lognormal) for proportions-at-age. Consequently, models with fixed M values were run, and although the age data were reasonably well fitted, the model failed to accurately represent declines in resource abundance that appear evident from CPUE values, which have been declining since 2001. As a consequence the model was considered unsuitable for the provision of management advice.

The last stock assessment for LIN 7CK (Cook Strait) accepted by the Working Group was completed in 2010, and it is reported here. The stock assessment model partitions the population into two sexes, and age groups 3 to 25 with a plus group. The model’s annual cycle is described in Table 23 Year class strengths and fishing selectivity ogives were also estimated in the model. Commercial trawl selectivity was fitted as double normal curves; line fishery ogives were fitted as logistic curves.

For final runs, the full posterior distribution was sampled using Markov Chain Monte Carlo (MCMC) methods, based on the Metropolis-Hastings algorithm. Bounded estimates of spawning stock virgin (B_0) and current (B_{2008}) biomass were obtained. MCMC chains were constructed using a burn-in length of 4×10^6 iterations, with every 2000th sample taken from the next 20×10^6 iterations (i.e., a final sample of length 1000 was taken from the Bayesian posterior).

For LIN 7CK, model input data include catch histories, trawl and line fishery CPUE, extensive catch-at-age data from the trawl fishery, sparse catch-at-age data from the line fishery, and estimates of biological parameters. Initial modelling investigations found that the line CPUE produced implausible results; this series was rejected as a useful index. The base case used all catch-at-age data from the fisheries, and the trawl CPUE series. Instantaneous natural mortality was estimated in the model

Lognormal errors, with known CVs, were assumed for all CPUE and proportions-at-age observations. The CVs available for those observations allow for sampling error only. However, additional variance (termed process error), assumed to arise from differences between model simplifications and real world variation, was added to the sampling variance (Table 24).

LING (LIN)

Table 23: LIN 7CK — Annual cycle of the stock model, showing the processes taking place at each time step, their sequence within each time step, and the available observations. Fishing and natural mortality that occur within a time step occur after all other processes, with half of the natural mortality for that time step occurring before and half after the fishing mortality.

Step	Period	Processes	M^1	Age ²	Observations	
					Description	%Z ³
1	Oct–May	Recruitment fishery (line)	0.67	0.5	Line CPUE Line catch-at-age	0.5
2	Jun–Sep	increment ages fishery (trawl)	0.33	0	Trawl CPUE Trawl catch-at-age	0.5

^{1.} M is the proportion of natural mortality that was assumed to have occurred in that time step.

^{2.} Age is the age fraction, used for determining length-at-age, that was assumed to occur in that time step.

^{3.} %Z is the percentage of the total mortality in the step that was assumed to have taken place at the time each observation was made.

Table 24: LIN 7CK — Summary of the available data including source years (Years), and the estimated process error (CV) added to the observation error.

Data series	Years	Process error CV
CPUE (hoki trawl, Jun–Sep)	1994–2009	0.2
Commercial trawl proportion-at-age (Jun–Sep)	1999–2009	1.1
Commercial longline proportion-at-age	2006–07	1.1

The assumed prior distributions used in the assessment are given in Table 25. Most priors were intended to be relatively uninformed, and were specified with wide bounds.

Table 25: LIN 7CK — Assumed prior distributions and bounds for estimated parameters in the assessments. The parameters are mean (in log space) and CV for lognormal, and mean and standard deviation for normal.

Parameter description	Distribution	Parameters		Bounds	
		Mean	CV	Mean	SD
B_0	uniform-log	–	–	2 000	60 000
Year class strengths	lognormal	1.0	0.9	0.01	100
CPUE q	uniform-log	–	–	1e-8	1e-2
Selectivities	uniform	–	–	0	20–200*
M	lognormal	0.18	0.16	0.1	0.3

* A range of maximum values was used for the upper bound

Penalty functions were used to constrain the model so that any combination of parameters that did not allow the historical catch to be taken was strongly penalised. A small penalty was applied to the estimates of year class strengths to encourage estimates that averaged to 1.

The catch history, biological input parameters, and estimates of relative abundance used in the model are shown in Tables 4–7.

4.7.2 Model estimates

A single model was presented incorporating a catch history, trawl and line fishery catch-at-age, trawl CPUE series, with double-normal ogives for the trawl fishery and logistic ogives for the line fishery, and M estimated in the model.

Posterior distributions of LIN 7CK year class strength estimates from the base case model run are shown in Figure 15.

Figure 15: LIN 7CK — Estimated posterior distributions of year class strength. The horizontal line indicates a year class strength of one. Individual distributions show the marginal posterior distribution, with horizontal lines indicating the median.

The assessment is driven by the trawl fishery catch-at-age data and tuned by the trawl CPUE. Both input series contain information indicative of an overall stock decline in the last two decades. The confidence bounds around biomass estimates are wide (Table 26 Figure 16). Probabilities that current and projected biomass will drop below selected management reference points are shown in Table 27. Median M was estimated to be 0.24 (95% confidence interval 0.16–0.30). Estimates of biomass are very sensitive to small changes in M , but clearly there is information in the model encouraging an M higher than the ‘default’ value of 0.18. The model indicated a slight overall biomass decline to about 2000, followed by a much steeper decline from 2000 to 2010. Exploitation rates (catch over vulnerable biomass) were very low up to the late 1980s, and have been low to moderate (up to about 0.12 yr⁻¹) since then (Figure 17). Since the early 1990s, trawl fishing pressure has generally declined, while line pressure has generally increased.

Table 26: LIN 7CK — Bayesian median and 95% credible intervals (in parentheses) of B_0 and B_{2010} (in tonnes), and B_{2010} as a percentage of B_0 for all model runs.

Model run	B_0		B_{2010}		$B_{2010} (\%B_0)$	
Base case	8 070	(5 290–53 080)	4 370	(1 250–40 490)	54	(23–80)

Table 27: LIN 7CK — Probabilities that current (B_{2010}) and projected (B_{2015}) biomass will be less than 40%, 20% or 10% of B_0 . Projected biomass probabilities are presented for two scenarios of future annual catch (i.e., 220 t, and 420 t).

Biomass	Management reference points		
	40% B_0	20% B_0	10% B_0
B_{2010}	0.248	0.006	0.000
B_{2015} , 220 t catch	0.179	0.010	0.000
B_{2015} , 420 t catch	0.328	0.094	0.019

Figure 16: LIN 7CK — Estimated median trajectories (with 95% credible intervals shown as dashed lines) for absolute biomass and biomass as a percentage of B_0 .

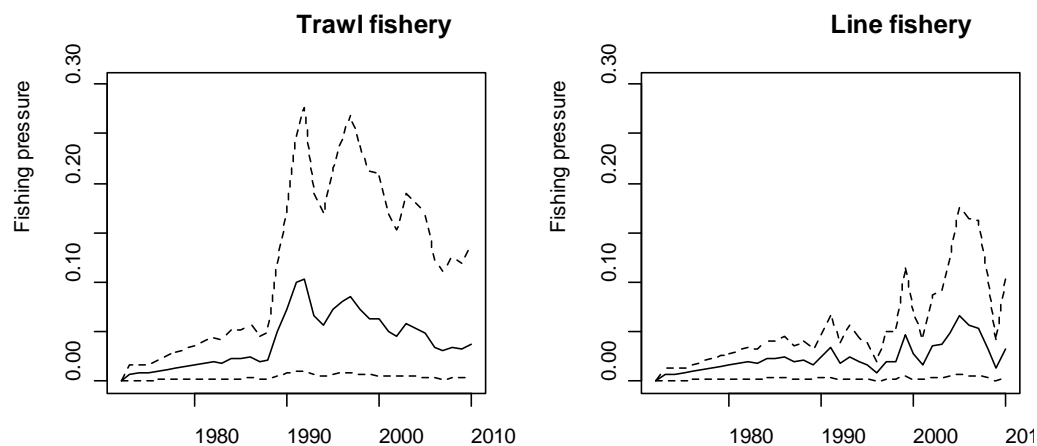

Figure 17: LIN 7CK — Estimated median trajectories (with 95% credible intervals shown as dashed lines) of fishery exploitation rates.

Estimates of biomass projections derived from this assessment are shown below (Section 4.9).

4.9 Projections

Projections for LIN 6B from the 2006 assessment are shown in Table 28. The LIN 6B stock (Bounty Plateau) is likely to decline out to 2011, but probably will still be higher than 50% of B_0 . Projections out to 2015 for LIN 7CK indicate that biomass is likely to increase with future catches equal to recent catch levels, or decline slightly if catches are equal to the mean since 1990 (Table 29). New projections made in 2011 out to 2016 for LIN 3&4 and 5&6, assuming future annual catches equal to recent catch levels, are shown in Table 30. For LIN 3&4, stock size is likely to remain about the same. For LIN 5&6, stock size is likely to increase slightly. For LIN 7 WC the Working Group did not consider that projections using either run were reliable and so no projections are shown.

Table 28: LIN 6B Bayesian median and 95% credible intervals (in parentheses) of projected B_{2011} , B_{2011} as a percentage of B_0 , and B_{2011}/B_{2006} (%) for the 2006 base case.

Stock and model run		Future catch (t)	B_{2011}		$B_{2011} (\%B_0)$		$B_{2011}/B_{2006} (\%)$	
LIN 6B	Base case	600	7 460	(2 950–18 520)	53	(26–116)	86	(51–168)

Table 29: LIN 7CK Bayesian median and 95% credible intervals (in parentheses) of projected B_{2015} , B_{2015} as a percentage of B_0 , and B_{2015}/B_{2010} (%) for the base case.

Stock and model run		Future catch (t)	B_{2015}		$B_{2015} (\%B_0)$		$B_{2015}/B_{2010} (\%)$	
LIN 7CK	Base case	220	5 030	(1 310–43 340)	59	(24–97)	110	(82–158)
		420	4 320	(590–42 910)	52	(11–92)	95	(45–136)

5. ANALYSIS OF ADAPTIVE MANAGEMENT PROGRAMMES (AMP)

The Ministry of Fisheries revised the AMP framework in December 2000. The AMP framework is intended to apply to all proposals for a TAC or TACC increase, with the exception of fisheries for which there is a robust stock assessment. In March 2002, the first meeting of the new Adaptive Management Programme Working Group was held. Two changes to the AMP were adopted:

- a new checklist was implemented with more attention being made to the environmental impacts of any new proposal;
- the annual review process was replaced with an annual review of the monitoring requirements only. Full analysis of information is required a minimum of twice during the 5 year AMP.

LIN 1

In October 2002, the TACC for LIN 1 was increased from 265 t to 400 t within the AMP. A full-term review of the LIN 1 AMP was carried out in 2007.

Mid-term Review 2009 (AMP WG/09/09).

Fishery Characterization

- LIN 1 entered the QMS in 1986–87 at a TACC of 200 t, which was increased to 238 t in 1988–89 and 265 t in 1989–90, probably due to the quota appeal process. LIN 1 catches remained slightly under the TACC up to 1995–96, but then exceeded the TACC, reaching about 300 t over most of the period 1996–97 to 2001–02. LIN 1 entered the AMP programme in 2002–03, with a TACC increase from 265 t to 400 t.
- After implementation of the AMP, catches dropped back to the previous TACC level for two years, and then increased to 364 t by 2005–06, dipped to 201 t in 2006–07, and increased to 381 t in 2007–08, the highest catch level over the data series.

- 53% of LIN 1 landings come from the bottom trawl fishery and a further 46% by bottom longline since 1989–90. The remaining methods account for less than 2% of the total landings.
- Most BT and BLL landings come from the Bay of Plenty. The majority of bottom trawl catches are taken in Statistical Areas 008 to 010, although there have been significant bottom trawl catches of ling on the west coast of the North Island in some years in Areas 046 to 048. There were substantial ling by-catches made by trawl on the North Island west coast from 1996–97 to 2000–01 in the gemfish fishery (which has since ceased), and longline catches have increased from the East Northland area.
- Ling are caught in small quantities across many fisheries. The distribution of BT effort is broader than the distribution of catch, with effort taking some LIN 1 in East Northland and the west coast in most years. Bottom longline landings of LIN 1 have a wider distribution and are more sporadic, with the Bay of Plenty landings coming primarily from Areas 009 and 010. Bottom longline landings increased after about 2000 in East Northland Area 002, but have fallen off considerably in 2007–08.
- There is a small targeted ling trawl fishery, while trawl catches of LIN 1 are mainly made in the scampi and gemfish targeted fisheries. The gemfish fishery mainly contributed catches from 1996–97 to 2000–01 and has since considerably diminished with the reduction of the SKI 1 TACC. The Bay of Plenty scampi fishery has also changed considerably during this period, particularly after SCI entered the QMS, moving from a competitive fishery requiring multiple vessels to a more rationalised fishery requiring only a single vessel. In contrast, about 75% of the ling longline catch is taken in a targeted ling fishery, with only minor by-catches coming from bluenose, ribaldo and hapuku targeted longline fisheries.
- The bottom longline landings of LIN 1 are taken mainly in the final two months of the fishing year, probably due to the economics of the vessels switching from tuna longlining to cleaning up available quota at the end of the fishing year. Bottom trawl catches of ling tend to be more evenly distributed across the year and reflect the fishing patterns of the diverse trawl targets, such as scampi which is also a consistent fishery over the entire year. Both of the major fishing methods which take ling have sporadic seasonal patterns, reflecting the small landings in most years and the by-catch nature of many of the fisheries.

CPUE Analysis

Figure 18: LIN 1 CPUE analysis based on target ling bottom longline data stratified by trip, target species and statistical area for Statistical Areas 002, 003, 004, 008, 009 and 010 standardised with respect to fishing year, number of hooks, vessel, month and number of lines set. Indices from two unstandardised analyses are presented for comparison: a) “arithmetic”, the annual sum of landings divided by the total annual number of hooks; and b) “unstandardised”, the geometric mean of landings per hook by trip-stratum.

LING (LIN)

- The depth distribution of ling catches in the trawl fisheries shows two main depths associated with the target species. Most ling are caught in the scampi / hoki / ling fishery at about 400 m depth, but some are taken in the tarakihi / snapper / barracouta / trevally fisheries around 100 m depth. Bottom longline depth records indicate that target ling fishing (as well as target bluenose fishing) takes place at even deeper depths, with most of the records lying between 500 and 600 m.
- The WG has previously noted substantial problems with the quality of LIN 1 data. Estimated catches tend to be less than landed greenweight (the median landed greenweight is about 25% greater than the estimated catch in the same trip), but only 4% of trips by weight neglect to report estimated catches of ling when there are landings. The biggest problem with this data set is the confusion, largely confined to the period prior to about 1995–96, where the FMA has been reported as the statistical area of capture rather than the true statistical area. This is a problem for a LIN 1 analysis because (for instance) FMA 4 (Chatham Rise) will be included in this dataset because statistical area 004 is valid for LIN 1. It is not possible to independently validate such a report because the CELR reporting form used by these vessels does not require a noon position or some other corroborating evidence of location. This problem is further exacerbated because many trips which apparently are legitimately fishing in FMAs 1 and 9 (the two LIN 1 FMAs) also tend to range widely, circumnavigate the entire North Island and venture into South Island waters. There is a large amount of landings made to the intermediate destination code R (retained on board) which further confounds the analysis because this breaks the continuity of the landings with the effort section of the form, resulting in much of the data being excluded and severely limiting the amount of data available for CPUE analyses.
- The diverse nature and broad geographic range of the LIN 1 fisheries has further complicated the selection of representative CPUE indices. Eight potential fisheries were previously identified as potential CPUE indices, but none of the analyses were considered to be robust due to the diverse nature of the fisheries and relative paucity of data. The AMP WG concluded in 2007, when it last reviewed the LIN 1 fishery, that landed catch data were particularly unreliable, and recommended that estimated catch data should be used instead.
- The 2007 review of the LIN 1 CPUE indices concluded that the LIN bycatch fishery in the target scampi bottom trawl fishery in the Bay of Plenty and the target ling bottom longline fishery in the Bay of Plenty and East Northland had sufficient information to warrant attempting standardised CPUE analyses (Starr et al 2007).
- These two candidate CPUE analyses were updated for this review. However, noting that there is now only one vessel in the scampi fishery, and that the amount of LIN catch data from the scampi bycatch fishery continues to decrease, the WG concluded that the only candidate index of LIN 1 abundance worth considering in this review was the BLL(LIN) index (target ling fishing using bottom longline). The WG recommended that future analyses which included mixed target species bottom trawl effort should be investigated to replace the BT(SCI) index.
- In 2009, the BLL(LIN) index was updated to exclude vessels which only fished in a single year, and calculated alternately using estimated and landed catches. The updated BLL index essentially remains unchanged from the one presented in 2007, consisting of two periods of slowly declining CPUE from 1990–91 to 1996–97 and 1999–00 to 2005–06, separated by a strong, highly uncertain and likely anomalous peak in 1998–99.
- In 2007, the WG noted that BLL reporting rates greatly exceed landed catch weights, reaching 700% in 1998–99. The high CPUE peak in 1998–99 appeared to result from landings which occurred in a single month by two vessels which typically had high catch rates (Figure 18). Many new participants have entered and left this fishery and the vessel effect needs to be investigated further.
- The WG made a number of recommendations for additional data selection procedures and analyses to investigate vessel effects on the BLL(LIN) index (see below).

Status of the Stock

Analysis Recommendations

The following analyses were conducted or recommended during the 2009 review:

- The WG requested that the vessels which only fished in one year be removed from the analysis. This was done and updated analyses were presented to the review.

- At the next review, BLL index standardisations need to further explore the reasons for the peak in 1998–99 (which resulted only from two vessels which fished only two and four trip strata respectively). The linkage of core fleet vessels across this and the effect of inclusion of large autoliners in the BLL index also needs to be investigated.
- Other options should be explored for excluding autoliners or vessels which do not belong in FMA 1 during data extraction, and then modifying grooming procedures to retain a higher proportion of data for the remaining vessels.
- For future analyses, a mixed target BT(HOK,LIN,SKI) index should be calculated to replace the BT(SCI) index.

Abundance Indices

The WG concluded that the BT(SCI) index was not an appropriate index for LIN 1, and had numerous shortcomings related to limited number of vessels, particularly in the most recent four years and poor linkage across years. The BLL(LIN) target index appears to have more potential as an index for LIN 1, but shows an apparently anomalous peak in 1998–99 and also has a relatively small amount of data. If this anomalous peak is excluded, the BLL(LIN) index has been stable without trend since 1995–96. However, until the reasons for the peak in BLL CPUE are understood, the WG concluded that the CPUE indices from this series are not reliable indices of LIN 1 abundance.

Sustainability of Current Catches

In the absence of a representative index of abundance, it is not known whether current LIN 1 catches or the TACC are sustainable.

Stock Status

The state of the stock in relation to B_{MSY} is unknown.

6. STATUS OF THE STOCKS

Stock Structure Assumptions

Ling are assessed as six independent biological stocks, based on the presence of spawning areas and some differences in biological parameters between areas (Horn 2005).

The Chatham Rise biological stock comprises all of Fishstock LIN 4, and LIN 3 north of the Otago Peninsula. The Sub-Antarctic biological stock comprises all of Fishstock LIN 5, all of LIN 6 excluding the Bounty Plateau, and LIN 3 south of the Otago Peninsula. The Bounty Plateau (part of Fishstock LIN 6) holds another distinct biological stock. The WCSI biological stock occurs in Fishstock LIN 7 west of Cape Farewell. The Cook Strait biological stock includes those parts of Fishstocks LIN 7 and LIN 2 between the northern Marlborough Sounds and Cape Palliser. Ling around the northern North Island (Fishstock LIN 1) are assumed to comprise another biological stock, but there is no information to support this assumption. The stock affinity of ling in LIN 2 between Cape Palliser and East Cape is unknown.

LIN 1 Stock

Stock Status	
Year of Most Recent Assessment	2009
Assessment Runs Presented	None. Fishstock LIN 1 was managed under an AMP programme from 2003 to 2009.
Reference Points	Management Target: 40% B_0 Soft Limit: 20% B_0 Hard Limit: 10% B_0
Status in relation to Target	Unknown
Status in relation to Limits	Unknown
Historical Stock Status Trajectory and Current Status	-

LING (LIN)

Fishery and Stock Trends	
Recent Trend in Biomass or Proxy	Unknown
Recent Trend in Fishing Mortality or Proxy	Unknown
Other Abundance Indices	Two CPUE series have been estimated (scampi-targeted bottom trawl, and a ling targeted bottom longline), but neither are considered reliable.
Trends in Other Relevant Indicators or Variables	-

Projections and Prognosis	
Stock Projections or Prognosis	Unknown
Probability of Current Catch or TACC causing decline below Limits	Soft Limit: Unknown Hard Limit: Unknown

Assessment Methodology	
Assessment Type	Level 3 – Qualitative evaluation
Assessment Method	Evaluation of fishery trends.
Main data inputs	- CPUE series
Period of Assessment	Latest assessment: 2009 Next assessment: Unknown
Changes to Model Structure and Assumptions	No modeling completed.
Major Sources of Uncertainty	Only fishery dependent abundance series were available (CPUE), and these were not considered reliable. The biological stock affinities of ling in LIN 1 are unknown.

Qualifying Comments
In the absence of a representative and useful index of abundance, it is not known whether current LIN 1 catches or the TACC can be maintained without reducing the stock size. Current stock status is unknown.

Fishery Interactions
Ling are often taken as a bycatch in hoki target trawl fisheries, and scampi target trawl fisheries off northern New Zealand. Target line fisheries for ling have the main bycatch species of spiny dogfish, sea perch, sharks and skates and ribaldo. Bycatch species of concern include sharks, skates, fur seals and seabirds (trawl fisheries), and sharks, skates and seabirds (longline fisheries).

East coast North Island (part of LIN 2, statistical areas 11-15)

Stock Status	
Year of Most Recent Assessment	2014
Assessment Runs Presented	A CPUE time series based on bottom longline ling target fishing.
Reference Points	Target: 40% B_0 Soft Limit: 20% B_0 Hard Limit: 10% B_0 Overfishing threshold: F corresponding to 40% B_0
Status in relation to Target	Unknown. The CPUE has declined by between about 50–60% since the start of the time series in 1992.
Status in relation to Limits	B_{2014} is Unlikely (< 40%) to be below the Soft Limit and Very Unlikely (< 10%) to be below the Hard Limit.
Status in relation to Overfishing	Unknown

Historical Stock Status Trajectory and Current Status

Standardized CPUE index (\pm 95% CI) for bottom longline vessels targeting ling from the ECNI statistical areas 11-15 (1992-2013). The dashed horizontal line is the time series mean.

Fishery and Stock Trends

Recent Trend in Biomass or Proxy	Biomass is estimated to have declined from 1992 by between 50–60%.
Recent Trend in Fishing Intensity or Proxy	Unknown
Other Abundance Indices	-
Trends in Other Relevant Indicators or Variables	-

Projections and Prognosis

Stock Projections or Prognosis	-
Probability of Current Catch or TACC causing Biomass to remain below or to decline below Limits	Soft Limit: Unknown Hard Limit: Unknown
Probability of Current Catch or TACC causing Overfishing to continue or to commence	CPUE has declined while catches have been below the TACC. There is some probability that fishing at the TACC or current catch may lead to overfishing.

Assessment Methodology and Evaluation

Assessment Type	Level 2 – Partial quantitative stock assessment	
Assessment Method	Evaluation of a CPUE time series from 1992–2013 for bottom longliners targeting ling in statistical areas 11–15	
Assessment Dates	Latest assessment: 2014	Next assessment: Unknown
Overall assessment quality rank	1 – High Quality	
Main data inputs (rank)	- Bottom longline effort and estimated catch	1 – High Quality
Data not used (rank)	N/A	
Changes to Model Structure and Assumptions	-	

LING (LIN)

Major Sources of Uncertainty	It is assumed that the longline CPUE time series tracks the entire biomass of ling in this stock. The boundaries of this biological stock, particularly towards the Cook Strait, are uncertain.
------------------------------	--

Qualifying Comments
-

Fishery Interactions
Ling are often taken as a bycatch in hoki target trawl fisheries. Target line fisheries for ling have the main bycatch species of spiny dogfish, sea perch, sharks and skates and ribaldo. Low productivity species taken as incidental bycatch include sharks and skates. Incidental captures of protected species are reported for seabirds.

Chatham Rise (LIN 3 & 4)

Stock Status	
Year of Most Recent Assessment	2011
Assessment Runs Presented	A base case and one sensitivity run.
Reference Points	Management Target: 40% B_0 Soft Limit: 20% B_0 Hard Limit: 10% B_0
Status in relation to Target	B_{2011} was estimated to be about 55% B_0 ; Very Likely (> 90%) to be above the target
Status in relation to Limits	B_{2011} is Exceptionally Unlikely (< 1%) to be below the Soft Limit and Exceptionally Unlikely (< 1%) to be below the Hard Limit.

Fishery and Stock Trends	
Recent Trend in Biomass or Proxy	Biomass is very unlikely to have been below 40% B_0 . Biomass is estimated to have been increasing since 2003.
Recent Trend in Fishing Mortality or Proxy	Fishing pressure is estimated to have been declining since 1999.
Other Abundance Indices	-
Trends in Other Relevant Indicators or Variables	Recruitment since the early 1990s is estimated to have been fluctuating slightly around the long-term average for this stock.

Projections and Prognosis (2011)	
Stock Projections or Prognosis	Biomass is uncertain but current catch is unlikely to cause decline. Catches at level of the TACC have unknown prognosis.
Probability of Current Catch or TACC causing decline below Limits	Soft Limit: Exceptionally Unlikely (< 1%) at current catch Hard Limit: Exceptionally Unlikely (< 1%) at current catch

Assessment Methodology	
Assessment Type	Level 1 – Quantitative stock assessment
Assessment Method	Age-structured CASAL model with Bayesian estimation of posterior distributions.
Main data inputs	- Summer research trawl survey series, annually since 1992. - Proportions-at-age data from the commercial fisheries and trawl survey. - Line fishery CPUE series (annual indices since 1990). - Estimates of biological parameters
Period of Assessment	Latest assessment: 2011 Next assessment: 2014
Changes to Model Structure and Assumptions	No significant changes since the previous assessment, except that the line fishery CPUE index and composition data were excluded from the base case run.
Major Sources of Uncertainty	Estimates of current and virgin stock size are very imprecise.

Qualifying Comments
-

Fishery Interactions
Ling are often taken as a bycatch in hoki target trawl fisheries. Target line fisheries for ling have the main bycatch species of spiny dogfish, sea perch, sharks and skates and ribaldo. Bycatch species of concern include sharks, skates, fur seals and seabirds (trawl fisheries), and sharks, skates and seabirds (longline fisheries).

Sub-Antarctic (LIN 5 & 6)

Stock Status	
Year of Most Recent Assessment	2011
Assessment Runs Presented	A base case and one sensitivity run.
Reference Points	Management Target: 40% B_0 Soft Limit: 20% B_0 Hard Limit: 10% B_0
Status in relation to Target	B_{2011} was estimated to be between 70% and 101% B_0 ; Virtually Certain (> 99%) to be at or above the target
Status in relation to Limits	B_{2011} is Exceptionally Unlikely (< 1%) to be below the Soft Limit and Exceptionally Unlikely (< 1%) to be below the Hard Limit

Historical Stock Status Trajectory and Current Status

Trajectory over time of spawning biomass (absolute, and % B_0 , with 95% credible intervals shown as broken lines) for the Sub-Antarctic ling stock from the start of the assessment period in 1972 to the most recent assessment in 2007, for the base case model run. Years on the x-axis are fishing year with "1995" representing the 1994-95 fishing year. Biomass estimates are based on MCMC results.

Fishery and Stock Trends

Recent Trend in Biomass or Proxy	Biomass appears to have been increasing since 2000.
Recent Trend in Fishing Mortality or Proxy	Fishing pressure is estimated to have always been low, and declining since 1998.
Other Abundance Indices	–
Trends in Other Relevant Indicators or Variables	Recruitment throughout the 1980s was low relative to the long-term average for this stock, but has been average or better since 1993.

Projections and Prognosis

Stock Projections or Prognosis	Stock status is predicted to improve over the next 5 years at catch levels equivalent to that from recent years (i.e., 5900 t per year) or equivalent to the TACC (i.e., 12 100 t).
Probability of Current Catch or TACC causing decline below Limits	Soft Limit: Exceptionally Unlikely (< 1%) at current catch Hard Limit: Exceptionally Unlikely (< 1%) at current catch

Assessment Methodology

Assessment Type	Level 1 – Quantitative stock assessment	
Assessment Method	Age-structured CASAL model with Bayesian estimation of posterior distributions.	
Main data inputs	<ul style="list-style-type: none"> - Summer and autumn <i>Tangaroa</i> trawl survey series. - Proportions-at-age data from the commercial fisheries and trawl surveys. - Line fishery CPUE series (annual indices since 1991). - Estimates of biological parameters (but note that M was estimated in the models) 	
Period of Assessment	Latest assessment: 2011	Next assessment: 2014
Changes to Model Structure and Assumptions	No significant changes since the previous assessment, except that M was estimated as an ogive rather than being fixed at 0.18.	
Major Sources of Uncertainty	<p>The summer trawl survey biomass estimates are variable and catchability clearly varies between surveys. The general lack of contrast in this series (the main relative abundance series) makes it difficult to accurately estimate past and current biomass.</p> <p>The assumption of a single Sub-Antarctic stock (including the Puysegur Bank), independent of ling in all other areas, is the most parsimonious interpretation of available information. However,</p>	

	<p>this assumption may not be correct.</p> <p>Although the catch history used in the assessment has been corrected for some misreported catch (see Section 1.4), it is possible that additional misreporting exists.</p>
--	--

Qualifying Comments

Although estimates of absolute current and reference biomass are unreliable, B_0 was probably over 200 000 t. The stock has probably only been lightly fished.

Fishery Interactions

Ling are often taken as a bycatch in hoki target trawl fisheries. Target line fisheries for ling have the main bycatch species of spiny dogfish, sea perch, sharks and skates and ribaldo. Bycatch species of concern include sharks, skates, fur seals and seabirds (trawl fisheries), and sharks, skates and seabirds (longline fisheries).

Bounty Plateau (part of LIN 6)

Stock Status	
Year of Most Recent Assessment	2006
Assessment Runs Presented	A single model run
Reference Points	Management Target: 40% B_0 Soft Limit: 20% B_0 Hard Limit: 10% B_0
Status in relation to Target	B_{2006} was estimated to be 61% B_0 ; Very Likely (> 90%) to be at or above the target
Status in relation to Limits	B_{2006} is Very Unlikely (< 10%) to be below the Soft Limit and Exceptionally Unlikely (< 1%) to be below the Hard Limit.

Historical Stock Status Trajectory and Current Status

Trajectory over time of spawning biomass (absolute, and % B_0 , with 95% credible intervals shown as broken lines) for the Bounty Plateau ling stock from the start of the assessment period in 1980 to the most recent assessment in 2006. Years on the x-axis are fishing year with "1995" representing the 1994–95 fishing year. Biomass estimates are based on MCMC results.

Fishery and Stock Trends	
Recent Trend in Biomass or Proxy	Median estimates of biomass are unlikely to have been below 61% B_0 . Biomass is estimated to have been declining since 1999.
Recent Trend in Fishing Mortality or Proxy	Fishing pressure is estimated to have been low, but erratic, since 1980.
Other Abundance Indices	–
Trends in Other Relevant Indicators or Variables	Recruitment was above average in the early 1990s, but below average in the late 1990s. No estimates of recruitment since 1999 are available.

LING (LIN)

Projections and Prognosis (2006)	
Stock Projections or Prognosis	Stock status is predicted to continue declining slightly over the next 5 years at a catch level equivalent to the average since 1991 (i.e., 600 t per year).
Probability of Current Catch or TACC causing decline below Limits	Note that there is no specific TACC for the Bounty Plateau stock. Soft Limit: Very Unlikely (< 10%) Hard Limit: Very Unlikely (< 10%)

Assessment Methodology	
Assessment Type	Level 1 – Quantitative stock assessment
Assessment Method	Age-structured CASAL model with Bayesian estimation of posterior distributions.
Main data inputs	- Proportions-at-age data from the commercial line fishery. - Line fishery CPUE series (annual indices since 1992). - Estimates of biological parameters.
Period of Assessment	Latest assessment: 2006 Next assessment: Unknown
Changes to Model Structure and Assumptions	No significant changes since the previous assessment.
Major Sources of Uncertainty	There are no fishery-independent indices of relative abundance, so the assessment is driven largely by the line fishery CPUE series. Stock projections are based on a constant future catch of 600 t per year. However, historic catches from this fishery have fluctuated widely, so future catches could be markedly different from 600 t per year.

Qualifying Comments	
There is no separate TACC for this stock; it is part of the LIN 6 Fishstock that has a TACC of 8505 t.	
Fishery Interactions	
Target line fisheries for ling have the main bycatch species of spiny dogfish, sharks and skates and ribaldo. Bycatch species of concern include sharks, skates and seabirds.	

West coast South Island (LIN 7)

Stock Status	
Year of Most Recent Assessment	2013
Assessment Runs Presented	A base case and one sensitivity model run.
Reference Points	Target: 40% B_0 . Soft Limit: 20% B_0 . Hard Limit: 10% B_0 . Overfishing threshold: F corresponding to 40% B_0
Status in relation to Target	B_{2012} was estimated to be about 71% B_0 ; Very Likely (> 90%) to be at or above the target.
Status in relation to Limits	B_{2012} is Exceptionally Unlikely (< 1%) to be below the Soft Limit and Exceptionally Unlikely (< 1%) to be below the Hard Limit.
Status in relation to Overfishing	Unknown

Historical Stock Status Trajectory and Current Status

Trajectory over time of spawning biomass (absolute, and % B_0 , with 95% credible intervals shown as broken lines) for the WCSI ling stock from the start of the assessment period in 1972 to the most recent assessment in 2013. Years on the x-axis are fishing year with “1995” representing the 1994–95 fishing year. Biomass estimates are based on MCMC results.

Fishery and Stock Trends

Recent Trend in Biomass or Proxy	Biomass is estimated to have been declining
Recent Trend in Fishing Intensity or Proxy	Unknown
Other Abundance Indices	A CPUE index was available from the line (target) fishery but was not considered reliable. The time series of the inshore <i>Kaharoa</i> survey does not adequately cover the distribution of ling on the west coast.
Trends in Other Relevant Indicators or Variables	The age structures of both the commercial catch and trawl survey catch are broad, indicating a low exploitation rate.

Projections and Prognosis

Stock Projections or Prognosis	No projections were reported
Probability of Current Catch or TACC causing Biomass to remain below or to decline below Limits	Soft Limit: Unknown Hard Limit: Unknown
Probability of Current Catch or TACC causing Overfishing to continue or to commence	Unknown

Assessment Methodology and Evaluation

Assessment Type	Level 1 - Full quantitative stock assessment	
Assessment Method	Age-structured CASAL model with Bayesian estimation of posterior distributions	
Assessment Dates	Latest assessment: 2013	Next assessment: 2016
Overall assessment quality rank	1 – High Quality	
Main data inputs (rank)	- Catch history - Abundance index from two WCSI trawl surveys (2000, 2012) - Abundance index from the commercial trawl hoki-hake-ling target fishery CPUE - Proportions at age data from the commercial fisheries and trawl surveys - Estimates of fixed biological parameters	1 – High Quality 1 – High Quality 1 – High Quality 1 – High Quality 1 – High Quality
Data not used (rank)	Commercial line fishery CPUE	3 – Low Quality: does not track stock biomass

	<i>Kaharoa</i> trawl survey abundance index	3– Low Quality: inadequate spatial coverage of the stock distribution
Changes to Model Structure and Assumptions	Single sex model M estimated in the base case with an informed prior Reweighted sample sizes for age frequency data Inclusion of a relative trawl survey index with an informed prior on q .	
Major Sources of Uncertainty	There is inadequate contrast in the biomass indices to inform on the magnitude of the biomass. Although the catch history used in the assessment has been corrected for some misreported catch (see Section 1.4), it is possible that additional misreporting exists. It is assumed in the assessment models that natural mortality is constant over all ages. Trawl survey selectivity. YCS estimation for recent year classes is highly uncertain because it is based on only one survey.	

Qualifying Comments

This assessment is very uncertain but it is highly probable that B_{2012} is greater than 40% B_0 and it could be much higher.

Fishery Interactions

Ling are often taken as a bycatch in hoki target trawl fisheries. Target line fisheries for ling have the main bycatch species of spiny dogfish, sea perch, sharks and skates and ribaldo. Low productivity species taken as incidental bycatch include sharks and skates. Protected species interactions are reported for seabirds and fur seals.

Cook Strait (LIN 2 [stat area 16] & part of 7)

Stock Status

Year of Most Recent Assessment	2010 (an assessment in 2013 was rejected)
Assessment Runs Presented	A base case.
Reference Points	Target: 40% B_0 . Soft Limit: 20% B_0 . Hard Limit: 10% B_0 . Overfishing threshold: F corresponding to 40% B_0
Status in relation to Target	B_{2010} was estimated to be 54% B_0 ; Likely (> 60%) to be at or above the target.
Status in relation to Limits	B_{2010} is Exceptionally Unlikely (< 1%) to be below the Soft Limit and Exceptionally Unlikely (< 1%) to be below the Hard Limit.
Status in relation to Overfishing	Overfishing is Very Unlikely (< 10%) to be occurring.

Historical Stock Status Trajectory and Current Status

Trajectory over time of spawning biomass (absolute, and % B_0 , with 95% credible intervals shown as broken lines) for the Cook Strait ling stock from the start of the assessment period in 1972 to the most recent assessment in 2010. Years on the x-axis are fishing year with “1995” representing the 1994–95 fishing year. Biomass estimates are based on MCMC results.

Fishery and Stock Trends	
Recent Trend in Biomass or Proxy	Biomass is estimated to have been declining since 1999, but is unlikely to have dropped below 30% B_0 .
Recent Trend in Fishing Intensity or Proxy	Overall fishing pressure is estimated to have been relatively constant since the mid 1990s, but has trended down for trawl and up for line.
Other Abundance Indices	–
Trends in Other Relevant Indicators or Variables	Recruitment from 1995 to 2006 was low relative to the long-term average for this stock. There are no estimates for the more recent year classes.

Projections and Prognosis	
Stock Projections or Prognosis	Stock status is predicted to improve slightly over the next 5 years at a catch level equivalent to that since 2006 (i.e., 220 t per year), or remain relatively constant at a catch equivalent to the mean since 1990 (i.e., 420 t per year).
Probability of Current Catch or TACC causing Biomass to remain below or to decline below Limits	Note that there is no specific TACC for the Cook Strait stock. Soft Limit: Catch 220 t, Very Unlikely (< 10%); Catch 420 t, Very Unlikely (< 10%). Hard Limit: Catch 220 t, Exceptionally Unlikely (< 1%); Catch 420 t, Very Unlikely (< 10%).
Probability of Current Catch or TACC causing Overfishing to continue or to commence	Very Unlikely (< 10%).

Assessment Methodology and Evaluation		
Assessment Type	Level 1 - Full quantitative stock assessment.	
Assessment Method	Age-structured CASAL model with Bayesian estimation of posterior distributions.	
Assessment Dates	Latest assessment: 2010	Next assessment: 2015
Overall assessment quality rank	3 – Low Quality: The only accepted relative abundance series (trawl fishery CPUE) was not well fitted. A subsequent assessment in 2013 was rejected by the Working Group.	
Main data inputs (rank)	<ul style="list-style-type: none"> - Proportions-at-age data from the commercial trawl fishery. - Proportions-at-age data from the commercial line fishery. - Trawl fishery CPUE series (annual indices since 1994). - Estimates of biological parameters. 	1 – High Quality 3 – Low Quality 2 – Medium Quality 1 – High Quality
Data not used (rank)	Line fishery CPUE	3 – Low quality: does not track stock biomass
Changes to Model Structure and Assumptions	No significant changes since the previous assessment.	
Major Sources of Uncertainty	<p>There are no fishery-independent indices of relative abundance. It is not known if the trawl CPUE series is a reliable abundance index.</p> <p>The stock structure of Cook Strait ling is uncertain. While ling in this area are almost certainly biologically distinct from the WCSI and Chatham Rise stocks, their association with ling off the lower east coast of the North Island is unknown.</p> <p>It is possible that trawl selectivity has varied over time, resulting in poor fits to some age classes in some years.</p> <p>Line fishery selectivity is based on only two years of catch-at-age data from the autoline fishery. No information is available from the 'hand-baiting' line fishery.</p>	

	The model is moderately sensitive to small changes in M , and M is poorly estimated.
--	--

Qualifying Comments

There is no separate TACC for this stock; it comprises parts of Fishstocks LIN 7 and LIN 2.

Fishery Interactions

Ling are often taken as a bycatch in hoki target trawl fisheries. Target line fisheries for ling have the main bycatch species of spiny dogfish, sea perch, sharks and skates. Low productivity species taken as incidental bycatch include sharks and skates. Protected species interactions are reported for seabirds and fur seals.

7. FUTURE RESEARCH

A review of the ling stock structure for LIN 2 should be completed before further assessments are conducted for this QMA.

LOOKDOWN DORY (LDO)*(Cyttus traversi)***1. FISHERY SUMMARY**

Lookdown dory was introduced into the Quota Management System (QMS) on 1 October 2004 with the allowances, TACs and TACCs in Table 1. It is currently managed as three stocks: LDO 1 which comprises FMAs 1-2 and 7-9; LDO 3 which comprises FMAs 3-6; and LDO 10 (Kermadec region).

Table 1: Recreational and customary non-commercial allowances, TACCs and TACs, by Fishstock, for lookdown dory.

Fishstock	Recreational Allowance	Customary non-commercial Allowance	TACC	TAC
LDO 1	0	0	168	168
LDO 3	0	0	614	614
LDO 10	0	0	1	1
Total	0	0	783	783

1.1 Commercial fisheries

Reliable landings data are available from 1989-90 onwards, after the introduction of Catch Landing Returns (CLRs) in the previous year (Table 2). Annual landings are also available from Licensed Fish Receiver Returns (LFRRs), and these agree well with CLR figures in most years (within 10%), but differ by 20-27% in 4 of the 12 years with comparable data (Table 3). Total landings (CLR) have increased steadily from 127 t in 1989-90 to 760 t in 2001-02. Estimated catch as a percentage of recorded landings were moderate in the early 1990s at 60-70%, but subsequently declined to around 30%. Lookdown dory will often not be included within the top five species in a trawl haul, but the reason for the declining percentage of landings recorded as catch is unknown.

Since entering the QMS, catches in LDO 1 have exceeded the TACC slightly in the 2005-06 and 2007-08 fishing years (Table 2). The TACC in LDO 3 has never been caught. This probably reflects the reduction in the size of the trawl fishery on the Chatham Rise where the greatest proportion of lookdown dory has been taken as bycatch. No catch has been reported from LDO 10. Figure 1 shows the historical landings and TACC values for LDO 1 and LDO 3.

There is a seasonal pattern of catch of lookdown dory on the west coast South Island in relation to target fishing for spawning hoki and hake in winter. Catches elsewhere are also dependent on fishing activity in target fisheries but, other than a slight decline in winter months in relation to the shift in area of operation of the hoki fleet, they tend to be less seasonal.

LOOKDOWN DORY (LDO)

Table 2: Reported domestic landings (t) of lockdown dory by Fishstock and TACC from 2004-05 to 2012-13.

Fishstock FMA	LDO1		LDO3		LDO10		Total	
	Landings	TACC	Landings	TACC	Landings	TACC	Landings	TACC

2001-02	760	-	254	33

-, data not available

Lookdown dory is generally caught by bottom trawling in depths of 200 to 800 m mainly as bycatch in the hoki fishery, but also in a variety of other target fisheries such as barracouta, hake, ling, scampi, squid and jack mackerel. A small amount of target fishing is reported from FMA 7. Most of the catch has come from FMA 3 (east coast South Island), FMA 4 (Chatham Rise), and FMA 7 (west coast South Island) (Table 4). Landings from around the North Island have been restricted mostly to a few tonnes each year from FMAs 1, 2, 8 and 9. In FMA 5 (Southland) and FMA 6 (Sub-Antarctic) landings have been in the order of 10-30 t over the past six years. 123 kg of lockdown dory were reported to have been caught from outside the New Zealand EEZ in the 2012–13 fishing year.

Table 4: Reported historic landings (rounded to nearest tonne) of lockdown dory by FMA and fishing year 1989-90 to 2003-04.

Year	FMA 1	FMA 2	FMA 3	FMA 4	FMA 5	FMA 6	FMA 7	FMA 8	FMA 9	FMA 10

1.2 Recreational fisheries

There is no quantitative information on recreational harvest levels of lockdown dory. Due to the offshore location and depth distribution of lockdown dory recreational catch is thought to be negligible.

Figure 1: Historical landings and TACC for the two main LDO stocks. Left to right: LDO1 (Challenger, Central, Auckland), and LDO3 (South East Chatham Rise, South East Coast, Sub Antarctic, Southland). Note that this figure does not show data prior to entry into the QMS.

1.3 Customary non-commercial fisheries

An estimate of current catch is not available but given the offshore location and depth distribution of lockdown dory customary non-commercial catch is thought to be negligible.

1.4 Illegal catch

Estimates of illegal catch are not available.

1.5 Other sources of mortality

There is no quantitative information on the level of other sources of mortality.

2. BIOLOGY

Lookdown dory (*Cyttus traversi*) belongs to the family Zeidae. This family includes 13 species in seven genera distributed among the Atlantic and Pacific Oceans and the Mediterranean Sea. Lookdown dory also occurs in Australian waters, mostly east and south of Tasmania (where it is known as king dory), and also in South Africa. It is widely distributed throughout New Zealand waters with most records from the Chatham Rise. The geographical and depth distribution of immature (< 33 cm) fish is similar to that of adults (Hurst et al, 2000).

It is one of the less abundant members of a loosely associated group of about 23 common species, which together form the upper slope assemblage of New Zealand's continental shelf (Francis et al, 2002). The main species in this group are hoki, javelin fish, ling, pale ghostshark, sea perch, hake, and longnose spookfish (chimaerid). It was identified as a key species characterising the demersal fish community 350-550 m on the Chatham Rise (Bull et al, 2001).

Juveniles are found in surface waters up to a length of approximately 12 cm (May & Maxwell 1986), at which stage a metamorphosis occurs associated with the transition from a pelagic to a demersal habitat (James 1976). Adults are most common between 400 to 600 m, but have a wide depth range, from 50 to 1200 m (Anderson et al, 1998). Immature fish less than 33 cm have a similar geographical and depth distribution to adults (Hurst et al, 2000, O'Driscoll et al, 2003). The main prey of lookdown dory are natant decapod crustaceans, followed by euphausiid, mysid, galatheid, and nephropsid crustaceans, and fish (Clark & King 1989, Forman & Dunn, 2010). Lookdown dory is likely to be prey of larger fish and have occasionally been recorded in the stomachs of large ling.

LOOKDOWN DORY (LDO)

Trawl survey catch distribution across the Chatham Rise is fairly even, with females ranging from 10 to 55 cm total length, and males ranging from 10 to 45 cm. Lookdown dory show early signs of ripening to spawn in the January surveys (Livingston et al, 2002). Catch distribution across the Sub-Antarctic is patchier than across the Chatham Rise, particularly during autumn surveys (O’Driscoll & Bagley 2001). Lookdown dory appear to grow larger in the SubAntarctic than on the Chatham Rise with females ranging from 12 to 60 cm total length, and males ranging from 12 to 45 cm.

There are no known aggregations or migrations associated with spawning lookdown dory. Around the North Island, female lookdown dory were reported to mature at about 35 cm (May & Maxwell 1986). Ripe specimens are usually seen in autumn and winter but have also been observed in summer (Clark & King 1989). Livingston et al, (2002) reported early signs of ripening in January Chatham Rise trawl surveys. Observer records from the east coast South Island and Chatham Rise show that ripe females are more common in summer months and spent females are more common in winter (MacGibbon et al, 2012). Females on the west coast South Island are mostly resting, immature or spent in winter. Although most spawning takes place in autumn and winter it is likely that it is not a discrete event but occurs over much of the year. Research data from other areas are sparse, but show the presence of fish in spawning condition in most months of the year.

Although there are no published studies of validated age and growth of lookdown dory, preliminary work in Australia suggests this species may live to over 30 years (Stewart & Smith 1992). Tracey et al (2007) attempted to use lead-radium techniques to validate ageing by zone counts of otoliths but were unsuccessful. Based on unvalidated zone counts, they observed maximum ages of 38 and 25 years for males and females respectively for New Zealand lookdown dory from the Chatham Rise. Von Bertalanffy growth parameters are given in Table 5 and length-weight parameters are given in Table 6.

Table 5: Summary of von Bertalanffy growth parameters for Chatham Rise lookdown dory. Source : Tracey et al, 2007. NB : Ageing in this study used unvalidated methods.

3. STOCKS AND AREAS

A catch-effort characterisation carried out in 2010 (MacGibbon et al, 2012) identified three main fishing areas where lookdown dory are caught. These are the east coast South Island (FMA 3), Chatham Rise (FMA 4), and west coast South Island (FMA 7). It was found that these are still the main relevant fishing areas when this work was updated in 2012 (Ballara 2013, submitted).

There is little information on stock structure, recruitment patterns, or other biological characteristics on which to base any biological fishstock boundaries. MacGibbon et al (2012) found both sexes grow to a larger size in the SubAntarctic compared with the Chatham Rise suggesting the possibility of different stocks. There is also a difference in abundance between males and females in both areas with females nearly always outnumbering males (Figure 2).

Figure 2: Doorspread biomass estimates of lockdown dory by sex from the Chatham Rise 1991 to 2014 (upper) and SubAntarctic 1991 to 1993 and 2000 to 2012 (lower), from *Tangaroa* surveys.

4. STOCK ASSESSMENT

In December 2013 the Middle Depths Working Group agreed that for the west coast South Island (FMA 7, which accounts for the vast majority of the LDO 1 catch), acceptable methods of monitoring abundance are relative biomass estimates from the west coast South Island winter trawl survey carried out by R.V. *Tangaroa*. Catch-per-unit-effort indices from daily processed commercial catches and from the scientific observer programme were also accepted as indices of abundance for the west coast of the South Island.

The Middle Depths Working Group agreed in February 2011 that relative biomass estimates of lockdown dory from middle depth trawl surveys on the Chatham Rise and the Sub-Antarctic were suitable for monitoring major changes in lockdown dory abundance for LDO 3. Standardised CPUE

LOOKDOWN DORY (LDO)

indices from a mixed target species trawl fishery on the ECSI and Chatham Rise area were not accepted by the Working Group.

4.1 Estimates of fishery parameters and abundance

Lookdown dory biomass is usually in the top 10 species on the Chatham Rise and CVs are relatively precise (usually < 15%) (Table 7). Females have consistently comprised more of the biomass than males (Figure 2). Biomass indices on the Sub-Antarctic have higher but still acceptable CVs (generally < 30%). Relative biomass has been lower in the last two surveys. Biomass indices from the west Coast South Island are considerably lower than those for the Chatham Rise and SubAntarctic but are still thought to be reliable measures of abundance.

Table 7: Biomass indices (t) and coefficients of variation (cv) for lookdown dory from *Tangaroa* trawl surveys (Assumptions: areal availability, vertical availability and vulnerability = 1). NB: estimates are for the core strata only for the respective time series.

Length frequencies of Chatham Rise lookdown dory suggest that recruitment is variable (MacGibbon et al, 2012, Ballara, submitted). Generally, when a strongly recruiting year class is present, the male

length frequencies are often bimodal and females show two or three modes. Length frequency plots show that females are usually more numerous than males with a mean ratio for the time series of 1.15 females to every male (range 0.98-1.52). Males don't grow as large as females, with few males growing larger than 40 cm.

Length frequencies from the summer Sub-Antarctic series are less informative and no tracking of cohorts is possible. Overall, scaled population numbers are much lower for both sexes here than on the Chatham Rise but, again, females are more numerous than males with a mean ratio for the time series of 1.8 females for every male (range 0.55-3.9). Females also grow to a larger size than males and both sexes grow to a larger size on the Sub-Antarctic than on the Chatham Rise, which suggests that it may be a separate biological stock. This could also potentially be due to real differences in fishing pressure.

CPUE indices for lockdown dory on the WCSI were developed using the daily processed catch data and a smaller subset of observed vessels in the hoki and hake target fisheries. Both series show a similar trend, flat since 1995 (Figures 3 and 4).

Figure 3: Log normal CPUE indices for WCSI daily processed catch, bottom trawl target hoki or hake, showing catches (scaled to same mean as indices), and lognormal standardised and un-standardised indices. Bars indicate 95% confidence intervals. Year defined as June–September.

Figure 4: CPUE lognormal indices for WCSI observer programme data, target hoki or hake, bottom and midwater trawl, showing catches (scaled to same mean as indices), and lognormal standardised and un-standardised indices. Bars indicate 95% confidence intervals. Year defined as June–September.

LOOKDOWN DORY (LDO)

4.2 Yield estimates and projections

MCY cannot be estimated.

CAY cannot be estimated.

4.4 Other yield estimates and stock assessment results

No information is available.

5. STATUS OF THE STOCK

There are no known sustainability concerns in the lockdown dory fishery. For LDO 1, the area which accounts for the vast majority of the lockdown dory catch is thought to be well monitored by trawl surveys which are currently too short to suggest any pattern, but CPUE indices suggest that abundance has been stable since the mid-1990s. For LDO 3, trawl surveys on the Chatham Rise and Sub-Antarctic indicate abundance has fluctuated in both areas

Fishery and Stock Trends	
Recent Trend in Biomass or Proxy	Within LDO 1, FMA 7 biomass indices from the trawl survey time series are similar for 2000 and 2012, with an increase in 2013. This time series is only three points, but is thought to cover an appropriate depth and geographical range for lockdown dory. CPUE indices have been relatively flat since the mid-1990s.
Recent Trend in Fishing Mortality or Proxy	Unknown

Projections and Prognosis	
Stock Projections or Prognosis	Stock size is unlikely (< 40%) to change much at current catch levels in FMA 7.
Probability of Current Catch or TACC causing decline below Limits	Soft Limit: Unknown Hard Limit: Unlikely (< 40%)

Assessment Methodology	
Assessment Type	Level 2: Partial quantitative stock assessment
Assessment Method	Evaluation of agreed CPUE indices and trawl survey indices thought to index abundance within FMA 7 of LDO 1. The vast majority of the LDO 1 catch is taken in FMA 7, catches in other areas of LDO 1 are minor.

Fishery Interactions
In LDO 1, lockdown dory are taken primarily as bycatch in the bottom trawl west coast South Island hoki and hake target fisheries. Smaller catches are reported by midwater trawl. Interactions are the same as those for the hoki fishery. The east coast North Island scampi fishery also catches lockdown dory. A variety of other target fisheries also report catching lockdown dory but in very small amounts. A small amount of lockdown dory is targeted on the west coast of the South Island by smaller trawlers.

- **LDO 3 (Chatham Rise & Sub-Antarctic)**

Stock Status	
Year of Most Recent Assessment	2013
Reference Points	Target: Not established but 40% B_0 assumed Soft Limit: 20% B_0 Hard Limit: 10% B_0
Status in relation to Target	Unknown
Status in relation to Limits	Unknown for Soft limit Unlikely (< 40%) to be below the Hard Limit

Historical Stock Status Trajectory and Current Status

Doorspread biomass estimates of lookdown dory (error bars are ± two standard deviations) from the Chatham Rise, from *Tangaroa* surveys from 1991 to 2013.

Doorspread biomass estimates of lookdown dory (error bars are ± two standard deviations) from the SubAntarctic, from *Tangaroa* surveys from 1991 to 1993, 2000 to 2009, and 2011–12.

Fishery and Stock Trends

Recent Trend in Biomass or Proxy	Within LDO 3, FMAs 3 & 4 biomass indices have been fairly flat throughout the time series of Chatham Rise trawl surveys with the exception of 2010 and 2011 which show a decline. The 2012–14 surveys are more in line with previous years. For FMAs 5 & 6 biomass indices from the Sub-Antarctic series declined to 2002, steadily increased until 2009, and has dropped to the lowest estimates in the time series in 2011 and 2012.
Recent Trend in Fishing Mortality or Proxy	Unknown

Projections and Prognosis

Stock Projections or Prognosis	Stock size is Unlikely (< 40%) to change much at current catch levels in FMAs 5 & 6.
Probability of Current Catch or TACC causing decline below Limits	Soft Limit: Unknown Hard Limit: Unlikely (< 40%)

Assessment Methodology	
Assessment Type	Level 2: Partial quantitative stock assessment
Assessment Method	Evaluation of agreed trawl survey indices thought to index FMA 3 & 4, and FMA 5 & 6 abundance
Main data inputs	–
Period of Assessment	Latest assessment: 2013 Next assessment: 2016
Changes to Model Structure and Assumptions	-
Major Sources of Uncertainty	-

Qualifying Comments
There is some indication that lockdown dory on the Chatham Rise may be a different stock to the Sub-Antarctic (i.e. different maximum sizes, evidence of some spawning activity in the Sub-Antarctic, as well as more extensively on the Chatham Rise)

Fishery Interactions
In LDO 3 lockdown dory are mainly caught as bycatch in the hoki target bottom trawl fishery but also in many other middle depth fisheries. Interactions are the same as those for the hoki fishery.

ORANGE ROUGHY (ORH)

(Hoplostethus atlanticus)

1. INTRODUCTION

Orange roughy was introduced into the Quota Management System (QMS) on 1 October 1986. The main orange roughy fisheries have been treated separately for assessment and management purposes, and individual reports have been produced for each of six areas consisting of one or more stocks as follows:

1. Northern North Island (ORH 1)
 - Mercury-Colville stock
 - Other stocks
2. Cape Runaway to Banks Peninsula (ORH 2A, 2B, & 3A)
 - East Cape stock
 - Mid-East Coast stock
3. Chatham Rise and Puysegur (ORH 3B)
 - Northwest Chatham Rise stock
 - East and South Chatham Rise stock
 - Puysegur stock
 - Other minor stocks or subareas
4. Challenger Plateau (ORH 7A)
5. West coast South Island (ORH 7B)
6. Outside the EEZ
 - Lord Howe
 - Northwest Challenger
 - Louisville
 - West Norfolk
 - South Tasman

Four new stock assessments were conducted in 2014: Mid-East Coast, Northwest Chatham Rise, East and South Chatham Rise, and Challenger Plateau. All assessments used similar methods and relied on the use of ageing data and recent acoustic surveys of spawning plumes. The methods, which were common to the assessments, are described later in this introduction and a brief summary of the main results is also provided.

2. BIOLOGY

Orange roughy inhabit depths between 700 m and at least 1500 m within the New Zealand EEZ. They are most abundant between about 800 m and 1200 m. Their maximum depth range is unknown.

Orange roughy are slow-growing, long-lived fish. On the basis of otolith ring counts and radiometric isotope studies, orange roughy may live up to 120–130 years. Age determination from otolith rings has been validated by length-mode analysis for juveniles up to four years of age (Mace et al 1990), and adult ages have been validated using radiometric techniques in a study by Andrews & Tracey (2003).

Orange roughy otoliths have a marked transition zone in banding which is believed to be associated with the onset of maturity (Francis & Horn 1997). The estimates of transition-zone maturity range from 23 to 31.5 years for fish from various New Zealand fishing grounds (Horn et al 1998, Seafood Industry Council/NIWA unpublished data). However, spawning fish appear to be an older subset of the transition-zone mature fish as evidenced by the older ages and the larger sizes of fish caught on the spawning grounds. The age at which 50% of fish are spawning was estimated in the 2014 stock assessment models to range from 32–41 years (see Section 4.2). Orange roughy in New Zealand waters reach a maximum size of about 50 cm standard length (SL), and 3.6 kg in weight, but the maximum size appears to vary among local populations. Average size is around 35 cm SL, although there is variation between areas.

Spawning occurs once each year between June and early August in several areas within the New Zealand EEZ, from the Bay of Plenty in the north, to the Auckland Islands in the south. Spawning occurs in dense aggregations at depths of 700–1000 m and is often associated with bottom features such as pinnacles and canyons. Spawning fish are also found outside the EEZ on the Challenger Plateau, Lord Howe Rise, and Norfolk Ridge to the west, and the Louisville Ridge to the east.

Fecundity is relatively low, with females carrying on average about 40 000–60 000 eggs. The eggs are large (2–3 mm in diameter), are fertilised in the water column, and then drift upwards towards the surface and remain planktonic until they hatch close to the bottom after about 10 days. Details of larval biology are poorly known.

Orange roughy juveniles are first available to bottom trawls at age about 6 months, when they exhibit a mean length of about 2 cm. Juveniles have been found in large numbers in only one area, at a depth of 800–900 m about 150 km east of the main spawning ground on the north Chatham Rise.

Orange roughy also form aggregations outside the spawning period, presumably for feeding. Their main prey species include mesopelagic and benthopelagic prawns, fish and squid, with other organisms such as mysids, amphipods and euphausiids occasionally being important.

Natural mortality (M) has been estimated to be 0.045 yr^{-1} . This was based on otolith age data from a 1984 research survey of the Chatham Rise that used an estimation technique based on mean age. A similar estimate was obtained in 1998 from a lightly fished population in the Bay of Plenty.

Biological parameters used in the following assessments (Tables 1 and 2) were estimated by Doonan (1994) with modifications of A_r , A_m , S_r , and S_m for the 1998 stock assessment meetings by Francis & Horn (1997), Horn et al (1998), and Doonan et al (1998), and further modifications for the 2006 assessment by Hicks (2006).

Biases in reading ages from otoliths were identified, leading to a recommendation by reviewers of orange roughy workshops in October 2005 and February 2006 that no age data should be used in assessments until the biases were quantified and corrected. Stemming from this recommendation, a new ageing methodology was developed for orange roughy in 2007, associated with an international ageing workshop for this species (Tracey et al. 2007). In the 2014 stock assessments, age-frequency data were only used if the otoliths had been read using the new ageing protocol.

ORANGE ROUGHY (ORH)

It is believed that ages derived from otoliths collected during the 1984 and 1990 trawl surveys of the East Chatham Rise, which were aged under the old NIWA protocol do not contain serious biases. The single-sex growth curve, the length-weight parameters and the maturity ogive based on transition zones, which are all based on ageing using the old-protocol data are still believed to be valid. The estimates of these biological parameters (Table 1) were used for both the East Chatham Rise and the Northwest Chatham Rise stock assessments, although the otoliths used were collected from the East Chatham Rise only (of which most were from the Spawning Box). The transition-zone maturity estimates were not used in the 2014 stock assessments as maturity was estimated in each of the models.

Table 1: Biological parameters as used for orange roughy assessments. -, not estimated.

Table 2: Estimates of A_m and S_m by area for New Zealand orange roughy from transition zone observations.

Area	A_m			S_m		
	M	F	Both sexes	M	F	Both sexes
Chatham Rise (default)	-	-	29	-	-	3
Northwest Chatham Rise	-	-	28.51	-	-	4.56
East Chatham Rise	-	-	28.51	-	-	4.56
Ritchie Bank	-	-	31.5	-	-	7.11
Challenger Plateau	-	-	23	-	-	3
Puysegur Bank	-	-	27	-	-	3
Bay of Plenty	26	27	-	4	5	-

The method of Francis (1992) was used to estimate reference points and yields for orange roughy stocks. The differing parameter values in Tables 1 and 2 by stock meant that yield estimates varied across stocks (Table 3).

Table 3: Estimates of MCY , E_{CAY} and MAY for New Zealand orange roughy.

Area	MCY (% B_0)	E_{CAY}	MAY (% B_0)
Bay of Plenty (ORH 1)	1.47	0.063	1.94
Ritchie Bank (ORH 2A)	1.46	0.062	1.92
Chatham Rise (ORH 3B)	1.51	0.064	1.99
Puysegur Bank (ORH 3B)	1.47	0.062	1.94
Challenger Plateau (ORH 7A)	1.40	0.060	1.84

For all these stocks, the mean biomass when fishing using an *MCY* policy was estimated to be 51% of B_0 , and for a *CAY* policy it was 30% of B_0 (these values varied by less than 1% between the various stocks).

The reference points and yields given above are not used in the 2014 stock assessments. In these assessments, MCMC estimates of deterministic reference points and yields were made for the target biomass range of 30-40% B_0 . However, the lower bound of this range was taken from the above results (the mean biomass under a *CAY* policy).

3. ENVIRONMENTAL AND ECOSYSTEM CONSIDERATIONS

This section was updated for the 2013 Fishery Assessment Plenary after review by the Aquatic Environment Working Group. This summary is from the perspective of the deepwater trawl fisheries for orange roughy; an issue-by-issue analysis is available in the 2012 Aquatic Environment and Biodiversity Annual Review (www.mpi.govt.nz/Default.aspx?TabId=126&id=1644).

3.1 Role in the ecosystem

Orange roughy are the dominant demersal fish at depths of 750–1100 m on the north and east Chatham Rise, the east coast of the North Island south of about East Cape, and the Challenger Plateau (Clark et al 2000; Doonan & Dunn 2011; Tracey et al 1990). An analysis of New Zealand demersal fish assemblages using research trawl data showed that orange roughy was the most frequently occurring species (found in more than 40 % of tows) in the mid slope assemblage (Francis et al 2002). Fishing has reduced the abundance of orange roughy since the 1980s, and the effects of removing, for example, an average of about 18 000 t per year from ORH 3B between 1979–80 and 2009–10 are largely unknown. There are likely to have been ecosystem implications (Tracey et al 2012).

3.1.1 Trophic interactions

The main prey species of orange roughy include mesopelagic and benthopelagic prawns, fish and squid, with other organisms such as mysids, amphipods and euphausiids occasionally being important (Rosecchi et al 1988). Koslow (1997) showed that orange roughy have a faster metabolism than deepwater fishes that are typically dispersed over the flat seafloor, and their food consumption is higher. Ontogenetic shifts occur in their feeding preferences with the smaller fish (up to 20 cm) feeding on crustaceans, and larger fish (31 cm and above) feeding on teleosts and cephalopods (Stevens et. al 2011). Relative proportions of the three prey groups were similar between areas. Bulman & Koslow (1992) found that teleosts were more important than crustaceans by weight in the prey of Australian orange roughy, and that this dominance increased in adult-sized fish. Dunn & Forman (2011) inferred from diet analysis that juveniles feed more on the benthos compared with the benthopelagic foraging of adults. Where they co-occur, orange roughy and black oreo may compete for teleost and crustacean prey.

Predators of orange roughy are likely to change with fish size. Larger smooth oreo, black oreo and orange roughy were observed with healed soft flesh wounds, typically in the dorso-posterior region. Wound shape and size suggest they may be caused by one of the deepwater dogfishes (Dunn et al 2010). Giant squid and sperm whales have also been found to prey on orange roughy (Gaskin & Cawthorn 1967, Jereb & Roper 2010)

3.1.2 Ecosystem Indicators

Tuck et al (2009) used data from the Sub-Antarctic and Chatham Rise middle-depth trawl surveys to derive indicators of fish diversity, size, and trophic level. However, fishing for orange roughy occurs mostly deeper than the depth range of these surveys and is only a small component of fishing in the areas considered by Tuck et al (2009).

3.2 Incidental catch (fish and invertebrates)

Anderson (2011) summarised the bycatch of orange roughy and oreo trawl fisheries from 1990–91 to 2008–09. For orange roughy trawls since 2005–06, orange roughy accounted for about 84% of the total observed catch and the remainder comprised mainly oreos (10%), hoki (0.4%), and cardinalfish

ORANGE ROUGHY (ORH)

(0.3%). About 240 other species or species groups were recorded by observers, including various deepwater dogfishes (1.8%), rattails (1.0%), morid cods (0.8%), and slickheads (0.3%). Total annual bycatch in the orange roughy fishery has been as high as 27 000 t but has declined with the TACC and was less than 4000 t between 2005–06 and 2008–09 (non-commercial species comprising only 5–10% of the total). Total annual discards also decreased over time, from about 3400 t in 1990–91 to about 300 t in 2007–08 and, since about 2000, has been almost entirely of non-QMS species (rattails, shovelnose spiny dogfish, and other deepwater dogfishes).

Invertebrate species are caught in low numbers in the orange roughy fishery (Anderson 2011). Squid (mostly warty squid, *Moroteuthis* spp.) were the largest component of invertebrate catch, followed by various groups of coral, echinoderms (mainly starfish), and crustaceans (mainly king crabs, family Lithodidae). Tracey et al (2011) analysed the distribution of nine groups of protected corals based on bycatch records from observed trawl effort from 2007–08 to 2009–10, primarily from 800–1000 m depth. For the orange roughy target fishery, about 10% of observed tows in FMAs 4 and 6 included coral bycatch, but a higher proportion of tows in northern waters included coral (28% in FMA 1, 53% in FMA 9, Tracey et al 2011).

3.3 Incidental Catch (seabirds, mammals, and protected fish)

For protected species, capture estimates presented here include all animals recovered to the deck (alive, injured or dead) of fishing vessels but do not include any cryptic mortality (e.g., seabirds struck by a warp but not brought onboard the vessel, Middleton & Abraham 2007, Brothers et al 2010).

3.3.1 Marine mammal interactions

Trawlers targeting orange roughy have occasionally incidentally captured NZ fur seals (which were classified as “Not Threatened” under the New Zealand Threat Classification System in 2010, Baker et al 2010). Between 2002–03 and 2011–13, there were 6 observed captures of fur seals in the orange roughy trawl fisheries, with an estimated total capture of fur seals for all orange roughy tows between 2002–03 and 2012–13 of 11. (Table 4). All observed fur seal captures occurred in the Sub-Antarctic region. There have been no reported captures of fur seals in the last six years. The average rate of capture for 2002–03 to 2012–13 is 0.06 per 100 tows (range 0 to 0.28), a very low rate compared with other New Zealand trawl fisheries by between one and two orders of magnitude.

Table 4: Number of tows by fishing year and observed and model-estimated total NZ fur seal captures in the orange roughy trawl fisheries, 2002–03 to 2012–13. No. obs, number of observed tows; % obs, percentage of tows observed; Rate, number of captures per 100 observed tows, % inc, percentage of total effort included in the statistical model. Estimates are based on methods described in Thompson et al (2013) and available via <http://www.fish.govt.nz/en-nz/Environmental/Seabirds/>. Estimates from 2002–03 to 2011–12 are based on data version 20130304 and preliminary estimates for 2012–13 are based on data version 20140131.

† Provisional data, no model estimates available.

3.3.2 Seabird interactions

Annual observed seabird capture rates in the orange roughy trawl fisheries have ranged from 0.00 to 1.79 per 100 tows between 2002–03 and 2012–13 (Table 5). The average over this period is 0.48 per 100 tows, a very low rate relative to other trawl fisheries by between one and two orders of magnitude.

Table 5: Number of tows by fishing year and observed seabird captures in orange roughy trawl fisheries, 2002–03 to 2012–13. No. obs, number of observed tows; % obs, percentage of tows observed; Rate, number of captures per 100 observed tows. Estimates are based on methods described in Abraham et al (2013) and are available via <http://www.fish.govt.nz/en-nz/Environmental/Seabirds/>. Estimates from 2002–03 to 2011–12 are based on data version 20130304 and preliminary estimates for 2012–13 are based on data version 20140131.

2011–12	1 588	437	27.5	0	0.00	6	1 – 14	100.0
2012–13 [†]	1 592	184	11.6	2	1.09	-	-	-

[†] Provisional data, no model estimates available.

[‡] The two captures reported in the database v20130304 are updated to zero in version v20140131 which is likely to reduce the estimates of recent captures somewhat when these data are available; the associated capture rate will also be zero for this year.

Salvin's albatross was the most frequently captured albatross (38% of observed albatross captures, n=9) but seven different species have been observed captured since 2002–03. Cape petrels were the most frequently captured other taxon (57%, n=18 of non-albatross other birds, Table 6). Seabird captures in the orange roughy fisheries have been observed mostly around the Chatham Rise and off the east coast South Island. These numbers should be regarded as only a general guide on the distribution of captures because the observer coverage is not uniform across areas and may not be representative.

Table 6: Number of observed seabird captures in orange roughy fisheries, 2002–03 to 2012–13, by species and area. The risk ratio is an estimate of aggregate potential fatalities across trawl and longline fisheries relative to the Potential Biological Removals, PBR (from Richard & Abraham 2013 where full details of the risk assessment approach can be found). It is not an estimate of the risk posed by fishing for orange roughy. Other data, version 20140131.

Species	Risk Ratio	Chatham Rise	East Coast South Island	Subantarctic	Stewart Snares Shelf	West Coast South Island	Total
Salvin's albatross	Very high	8	0	1	0	0	9

White-faced storm petrel	-	1	0	0	0	0	1
Total other birds	N/A	15	9	0	0	0	24

Mitigation methods such as streamer (tori) lines, Brady bird bafflers, warp deflectors, and offal management are used in the orange roughy, oreo, and cardinalfish trawl fisheries. Warp mitigation was voluntarily introduced from about 2004 and made mandatory in April 2006 (Department of Internal Affairs, 2006). The 2006 notice mandated that all trawlers over 28 m in length use a seabird scaring device while trawling (being “paired streamer lines”, “bird baffler” or “warp deflector” as defined in the notice).

3.4 Benthic interactions

Orange roughy, oreo, and cardinalfish are taken using bottom trawls and accounted for about 14% of all tows reported on TCEPR forms to have been fished on close to the bottom between 1989–90 and 2004–05 (Baird et al 2011). Black et al (2013) estimated that, between 2006–07 and 2010–11, 98% of orange roughy catch was reported on TCEPR forms. Tows are located in Benthic Optimised Marine Environment Classification (BOMECE, Leathwick et al 2009) classes J, K (mid-slope), M (mid-lower slope), N, and O (lower slope and deeper waters) (Baird & Wood 2012), and 94% were between 700 and 1 200 m depth (Baird et al 2011). Deepsea corals in the New Zealand region are abundant and diverse and, because of their fragility, are at risk from anthropogenic activities such as bottom trawling (Clark & O’Driscoll 2003, Clark & Rowden 2009, Williams et al 2010). All deepwater hard corals are protected under Schedule 7A of the Wildlife Act 1953. Baird et al (2012) mapped the likely coral distributions using predictive models, and concluded that the fisheries that pose the most risk to protected corals are these deepwater trawl fisheries.

Trawling for orange roughy, like trawling for other species, is likely to have effects on benthic community structure and function (e.g., Rice 2006) and there may be consequences for benthic productivity (e.g., Jennings 2001, Hermsen et al 2003, Hiddink et al 2006, Reiss et al 2009). These consequences are not considered in detail here but are discussed in the Aquatic Environment and Biodiversity Annual Review 2013 (MPI, 2013).

The NZ EEZ contains 17 Benthic Protection Areas (BPAs) that are closed to bottom trawl fishing and include about 52% of all seamounts over 1500 m elevation and 88% of identified hydrothermal vents.

3.5 Other considerations

Fishing during spawning may disrupt spawning activity or success. Morgan et al (1999) concluded that Atlantic cod (*Gadus morhua*) “exposed to a chronic stressor are able to spawn successfully, but there appears to be a negative impact of this stress on their reproductive output, particularly through the production of abnormal larvae”. Morgan et al (1997) also reported that “Following passage of the trawl, a 300-m-wide “hole” in the [cod spawning] aggregation spanned the trawl track. Disturbance was detected for 77 min after passage of the trawl.” There is no research on the disruption of spawning orange roughy by fishing in New Zealand.

3.5.2 Genetic effects

Fishing, environmental changes, including those caused by climate change or pollution, could alter the genetic composition or diversity of a species. There are no known studies of the genetic diversity of orange roughy from New Zealand. Genetic studies for stock discrimination are reported under “stocks and areas”.

3.5.3 Habitat of particular significance to fisheries management

Habitat of particular significance for fisheries management (HPSFM) does not have a policy definition (MPI, 2013) although work is currently underway to generate one. Mace et al (1990) identified only one area of high abundance for juvenile orange roughy at 800–900 m depth about 150 km east of the main spawning ground on the north Chatham Rise. Orange roughy from 9 cm SL have also been located on the Challenger Plateau and O’Driscoll et al (2003) show other areas where immature fish are relatively common. Dunn et al (2009) showed that orange roughy juveniles are generally found close to the seabed, and in shallower water than the adults, starting off at depths of around 850–900 m and spreading deeper, and over a wider depth range, as they grow. Dunn & Forman (2011) also suggested that juveniles start on flat grounds shallower than the adults, that they shift deeper as they grow, and that seamounts and other features tend to be dominated by the largest orange roughy. It is not known if there are any direct linkages between the congregation of orange roughy around features and the corals found on those features. Bottom trawling for orange roughy has the potential to affect features of the habitat that could qualify as habitat of particular significance to fisheries management.

4. SUMMARY OF 2014 STOCK ASSESSMENTS

Stock assessments were undertaken for the Mid-east coast (MEC), Northwest Chatham Rise (NWCR), East and South Chatham Rise (ESCR) and ORH7A in 2014. In this section, the methods that were common to these four stock assessments are described and the main results are summarised.

4.1 Methods used in 2014

The methods used in 2014 were different from those used in previous orange roughy assessments in a number of respects. The major differences were in the application of a more stringent data quality threshold, in model structure, and in the use of age data to estimate year class strengths.

4.1.1 Data quality and model structure

A high threshold was imposed on data before they were used in an assessment. This resulted in the exclusion of a number of biomass estimates that had previously been used. In particular, CPUE indices were not used in any of the assessments because they were considered unlikely to be monitoring stock-wide abundance (e.g., non-spawning season catch rates from a single hill feature or complex within a large area cannot be monitoring stock wide abundance as the fishery would not have been sampling a large proportion of the stock; at best, such CPUE indices may index localised abundance; during the spawning season catches from a single hill or aggregation may be sampling a large proportion of the stock but the catch rates will depend on how the aggregation is fished rather than how much biomass is present). Also, estimates of biomass from egg surveys were not used as it was found that the available estimates were from surveys where the assumptions of the survey design were not met and/or there were major difficulties in analysing the survey data. Finally, acoustic-survey estimates of biomass were only used when mainly single-species aggregations were surveyed with suitable equipment. Estimates of spawning orange roughy biomass were accepted for plumes on the flat surveyed using hull-mounted transducers or towed systems, or for plumes on underwater features using towed systems only (otherwise the dead zone can be too large for reliable comparison).

Model structure was similar across the four assessed stocks. In each case, the base models were single-sex, single-area models with separate categories for age and maturity. Maturity was estimated within the model from age-frequencies of spawning fish and, if available, from female proportion spawning at age data from pre-spawning wide-area trawl surveys (available for NWCR and MEC). All mature fish were assumed to spawn each year as this was consistent with the estimates of female proportion spawning at age (see the NWCR and MEC assessments). This is a major contrast to earlier assessments where acoustic and egg survey estimates of spawning biomass were scaled up using estimates of transition-zone mature biomass before being used in an assessment. In the 2014 assessments, acoustic estimates of *spawning* biomass were used directly without scaling.

The use of age data was crucial to the success of the 2014 assessments. Model-based assessments of orange roughy stocks were abandoned in recent years because the model results were found to be insensitive to the data; i.e. results did not change whether or not recent abundance indices were included because the model assumptions - particularly the assumption of deterministic recruitment - overwhelmed the data. Age data were generally not used in these assessments because the (old) ageing methodology was considered unreliable, resulting in the unrealistic assumption of deterministic recruitment being used. This resulted in modelled biomass trajectories showing strong increasing trends as catches were scaled back but which were not supported by the fishery-independent abundance indices. The new ageing methodology (Tracey et al. 2007) has provided more reliable age data, which in turn has led to the abandonment of the deterministic recruitment assumption and models that fit trends in recent abundance indices.

4.1.2 Acoustic q priors

The major sources of recent abundance information in the models are acoustic surveys of spawning biomass. For each survey, the spawning biomass estimate was included in the appropriate assessment as an estimate of *relative* spawning biomass rather than *absolute* spawning biomass (the latter being used in previous assessments). The reason that the estimates are not used as absolute estimates of biomass is because there are two major potential sources of bias: (i) the estimates may be biased low

ORANGE ROUGHY (ORH)

or high because the estimate of orange roughy target strength is incorrect, and (ii) the survey is unlikely to have covered all of the spawning stock biomass. The unknown proportionality constant, or q , for each survey was estimated in the model using an informed prior for each q . Each prior was constructed from two components: orange roughy target strength and survey availability.

The target strength (TS) prior was derived from the estimates of Macaulay et al (2013) and Kloser et al (2013) who both obtained TS estimates (at 38 kHz) from visually verified orange roughy as they were herded by a trawl net (the “AOS” was mounted on the head of the net and acoustic echoes and stereo photos were obtained simultaneously). Macaulay et al (2013) estimated a TS (for 33.9 cm fish) of -52.0 dB with a 95% CI of -53.3 to -50.9 dB; Kloser et al (2013) gave a point estimate of -51.1 dB and gave a range, that allowed for the artificial tilt angles of the herded fish, from -52.2 to -50.7 dB. The prior was taken to be normal with a mean of -52.0 dB with 99% of the distribution covered by ± 1.5 dB (which covers both ranges). This results in a tight distribution for informed acoustic q priors, reflecting the high confidence in the target strength estimates.

For surveys that covered “most” of the spawning stock biomass (e.g., ESCR where in some years surveys covered the Old plume¹, the Rekohu plume, and the “Crack”), availability was modelled with a Beta(8,2) distribution (this has a mean of 0.8 – i.e., it is assumed *a priori* that 80% of the spawning stock biomass is being indexed). The acoustic q prior is the combination of the availability and TS priors (assuming they are independent). This was approximately normal with a mean of 0.8 and a CV of 19%. For surveys that were considered to have covered less than “most” of the spawning biomass, a similar prior was used for the q except that a lower mean value was assumed for the “availability” component of the prior (see individual assessments for how the mean was derived in these cases). When a higher CV was applied, the median estimates of biomass and stock status were slightly higher, and the confidence intervals were wider with a much higher upper bound.

4.1.3 Year class strength estimation

The number of year class strengths (YCSs) estimated within each model depended on the timing and number of age frequency observations available. In general a YCS was estimated provided that it was observed in at least one age frequency when it was neither “too old” nor “too young”. “Old” YCSs were not estimated because it was considered that there was too little information about these cohorts as only a few of them remained. “Too young” YCSs were not estimated because the selectivity for these ages is low and consequently the YCS estimates would be unreliable.

The Haist parameterisation for estimating YCS was used for all models (Bull et al 2012). In the 2013 MEC assessment it was found that the alternative Francis parameterisation unduly restricted YCS estimates as evidenced by poor fits to the trawl survey biomass indices. In contrast, the Haist parameterisation, using uniform priors, resulted in an excellent fit to the abundance indices at the MPD stage and an adequate fit at the MCMC stage. The YCS estimates were primarily driven by the composition data (age and length frequencies), but if they unduly penalised, the estimates are restricted to a space which does not allow the trawl biomass indices to be fitted well. In the 2014 assessments a “nearly uniform” prior was used with the Haist parameterisation: LN(mode = 1, log-space s.d. = 4).

4.1.4 Model runs

As far as was appropriate, a consistent set of sensitivity runs was conducted for each assessment. In addition to a base model, there were runs that estimated natural mortality (M); halved and doubled the recent acoustic biomass estimates (to show that the model was sensitive to recent biomass indices); assumed deterministic recruitment (to show the importance of estimating year class strengths); increased/decreased the mean of acoustic q priors; and two sensitivities that simultaneously increased/decreased M and decreased/increased the mean of the acoustic q priors by 20% (a lower stock status occurs when M is decreased and when the mean of the acoustic q priors is increased; similarly an increased stock status occurs for changes in the other direction). The runs estimating M (“EstM”) and those with the 20% changes in M and the mean of acoustic q priors (“LowM-Highq” and “HighM-Lowq”) were taken through to MCMC.

¹For clarity, what was previously described as the ‘Spawning plume’ located in the Spawning Box has been renamed the ‘Old-plume’ so as to differentiate it from the Rekohu plume, which is also a spawning plume.

4.1.5 Fishing intensity

Fishing intensity for each year of the assessment was measured in units of 100 – ESD (Equilibrium Stock Depletion). This quantity was estimated by running the model to deterministic equilibrium, given the exploitation rate and fishing pattern associated with each year. The equilibrium level of the spawning biomass will be the ESD for that year (e.g., if the stock is fished at a very high fishing intensity, the equilibrium spawning stock biomass will be close to zero: $ESD = 0\% B_0$; if the stock is being very lightly fished, then $ESD = 100\% B_0$). The quantity (100 – ESD) ranges from 0–100 with 100 denoting any pattern and level of fishing that would eventually force the stock down to zero spawning biomass. In general, the fishing intensity associated with a deterministic equilibrium of $x\% B_0$ is denoted as $U_{x\%B_0}$. To aid with the interpretation of fishing intensity in both the fishing intensity and “snail trail” plots (which have fishing intensity on the right hand y-axis), the value $U_{x\%B_0}$ has been replaced with an associated exploitation rate proxy on the left hand y-axis. Exploitation rate, expressed as a percentage, is the number of fish caught from every 100 available fish. The exploitation rate labels represent a median exploitation rate, as each $U_{x\%B_0}$ maps to a range of exploitation rates, rather than to a single number.

4.1.6 Projections

Projections were generally conducted over a 5-year time period at the level of the current catch and at the long-term yield associated with $U_{35\%B_0}$ (the fishing intensity associated with the mid-point of the target biomass range of 30–40% B_0). In each case, the random YCSs were brought in immediately after the last estimated YCS and were resampled from the last 10 years of estimates (this is done because YCSs are correlated rather than being independent from year to year). For long-term projections (e.g., for MEC to estimate T_{min} , the number of years required for the stock to be rebuilt when there is no fishing), the YCSs were resampled from all estimated YCSs to ensure that the resampled YCSs will average to near 1 (so that there is no implied regime shift). Projections were done for the base model and, as a “worse-case scenario”, for the *LowM-Highq* model.

4.2 Summary of 2014 stock assessment results

The main results of the 2014 stock assessments are summarised below: these include estimated natural mortality, maturity ogive parameter estimates, year class strength, virgin biomass, and stock status; deterministic B_{MSY} and MSY, and deterministic long-term yields at $U_{35\%B_0}$ (35% B_0 being the mid-point of the target biomass range).

For each of the four stock assessments the median estimate of natural mortality (M) from the “EstM” model was lower than the assumed value in the base model of 0.045 (Table 7). This was despite a fairly tight informed prior on M with a mean of 0.045 and $CV=0.15$. In each stock assessment there appears to be very little information in the data on the value of M ; this information can only come from the right-hand limb of age frequencies, where the relative proportion of old fish is related to M , but it is also confounded by fishing mortality, selectivity, and year class strength. It seems premature to move to a new value of M for the base models. However, as more age data are gathered the estimates of M may improve.

Table 7: Estimates of natural mortality for each stock assessed in 2014. These are MCMC estimates from the “EstM” models which are identical to the base models except that M is estimated using an informed prior $N(\text{mean} = 0.045, CV = 0.15)$

Stock	M (median)	95% CI
NWCR	0.041	0.033–0.051
ESCR	0.037	0.027–0.048
MEC	0.032	0.028–0.037
ORH7A	0.038	0.031–0.047

Estimates of the 50% maturity parameter (a_{50}) for the four stocks range from 32–41 years (Table 8). This is considerably older than the estimates of transition-zone maturity which range from 23–33 years (see Table 2). The slopes of the estimated maturity curves are also much shallower than those for transition-zone maturity (10–13 years from Table 8 compared to 3–7 years in Table 2).

ORANGE ROUGHY (ORH)

Table 8: Base model, median MCMC estimates of maturity for each stock assessed in 2014. a_{50} is the age, in the virgin population, at which 50% of the fish are mature; a_{t095} is the number of years that need to be added to a_{50} to get the age at which 95% of the fish are mature.

Stock	a_{50} (years)	a_{t095} (years)
NWCR	37	13
ESCR	41	12
MEC	35	10
ORH7A	32	10

There were some similarities in the estimates of year class strength (YCS) across the four stocks (Figure 1). The MEC assessment used the most age data and therefore it had the largest number of YCS estimated. Early YCS were generally estimated to be above average and recent YCS estimated to be below average. This same pattern was evident for ORH7A and ESCR (though over a shorter duration and of slightly lesser magnitude – see Figure 1). The NWCR was the only assessment where the pattern of recruitment was consistent with average (deterministic) recruitment (Figure 1).

Figure 1: MCMC base models: smoothed (where possible) median estimates of year class strength (YCS) for the four stocks assessed in 2014. A lowess smoother ($f = 0.15$) was applied to the MCMC median estimates for each cohort.

The estimated size of the four stocks varies considerably for both virgin and current biomass (Table 9). The ESCR stock had by far the largest virgin biomass, B_0 , estimated at over 300,000 t while the other stocks are smaller, with estimates of less than 100,000 t (Table 9). In terms of current biomass, three of the four stocks have median current biomass estimates within the 30–40% B_0 target range (Table 9, Figure 2). The fourth stock, the MEC stock, has a median estimate below the soft limit of 20% B_0 .

Table 9: Base case models, median MCMC estimates of virgin biomass (B_0), current biomass (B_{2014}) and current stock status (B_{2014}/B_0).

Stock	B_0 (000 t)	B_{2014} (000 t)	B_{2014} (% B_0)
NWCR	66	24	37
ESCR	320	93	30
MEC	95	14	14
ORH7A	88	37	42

Figure 2: MCMC base models: median estimates of stock status trajectory for the four stocks assessed in 2014. The biomass target range of 30–40% B_0 is shown by green lines, and the soft and hard limits by blue and red line respectively.

For each assessment, long-term deterministic projections were conducted for each posterior sample to determine the ESD and yield curves as a function of fishing intensity. This enabled estimation of deterministic reference points and yields (Table 10). Deterministic estimates of B_{MSY} are similar for all four stocks, falling within in the range 21.5-24.5% B_0 (Table 10). In each case, the expectation is that very little yield will be lost if the equilibrium biomass level increases from deterministic B_{MSY} to 35% B_0 (the mid-point of the biomass target range). The estimated long-term yields when fishing at U_{35} (the fishing intensity that forces the stock to deterministic equilibrium at 35% B_0) range from 1300–2100 t for the smaller stocks and is 7180 t for the ESCR stock (Table 10). These yield estimates are unrealistic in that they are derived using deterministic recruitment and maintaining an exact level of fishing intensity. More realistic estimates of long-term yield, such as those derived from a management strategy evaluation, would likely be lower.

Table 10: Base model, median MCMC estimates of deterministic B_{MSY} , MSY, deterministic long-term yield at $U_{35%B_0}$, and the exploitation rate corresponding to $U_{35%B_0}$.

Stock	B_{MSY} (% B_0)	MSY (% B_0)	$U_{35%B_0}$ yield (% B_0)	$U_{35%B_0}$ exploitation rate (%)	$U_{35%B_0}$ long-term yield (t)
NWCR	23.7	2.1	2.0	5.3	1320
ESCR	21.8	2.4	2.3	5.3	7180
MEC	22.5	2.3	2.2	5.1	2080
ORH7A	24.5	2.1	2.0	5.4	1740

5. FUTURE RESEARCH

More age information is needed for all stocks. For most areas, this may simply necessitate reading otoliths that have previously been collected. Increasing the number of years with age-composition data should enable better estimation of year class strengths, and should increase the number of YCSs able to be estimated.

For those stocks where the proportion spawning at age is used (e.g. MEC), investigate alternatives for estimating the proportion spawning at age given the sparse data; for example, consider making it asymptotic at a younger age.

The design and implementation of the Challenger (ORH 7A) combined trawl and acoustic survey needs to be reviewed to ensure that it is fit for purpose for future years.

ORANGE ROUGHY NORTHERN NORTH ISLAND (ORH 1)

1. FISHERY SUMMARY

1.1 Commercial fisheries

This region extends northwards from west of Wellington around to Cape Runaway. Prior to 1993–94 there was no established fishery, and reported landings were generally small (Table 1). A new fishery developed in winter 1994, when aggregations were fished on two hill complexes in the western Bay of Plenty. In 1996 catches were also taken off the west coast of Northland. Figure 1 shows the historical landings and TACC values for ORH 1.

A TACC of 190 t was set from 1989–90. Prior to that there had been a 10 t TAC and various levels of exploratory quota. From 1995–96, ORH 1 became subject to a five year adaptive management programme, and the TACC was increased to 1190 t. A catch limit of 1000 t was applied to an area in the western Bay of Plenty (Mercury-Colville ‘box’), with the former 190 t TACC applicable to the remainder of ORH 1. In 1994 and 1995, research fishing was also carried out under Special Permit (not included in the TACC). For the period June 1996–June 1997, a Special Permit was approved for exploratory fishing. This allowed an additional 800 t (not included in the TACC) to be taken in designated areas, although catches were limited from individual features (hills and seamounts etc).

Table 1: Reported landings (t) and TACCs (t) from 1982–83 to 2012–13. - no TACC. The reported landings do not include catches taken under an exploratory special permit of 699 t in 1998–99 and 704 t in 1999–2000. QMS data from 1986-present.

Fishing year	Reported landings			
	West coast	North-east coast	Total	TACC
1982–83*	< 0.1	0	< 0.1	-
1983–84*	0.1	0	0.1	-
1984–85*	< 0.1	96	96	-
1985–86*	< 1	2	2	-
1986–87*	0	< 0.1	< 0.1	10
1987–88	0	0	0	10
1988–89	0	19	19	10

2012–13	+	+	1 171	1 400

* FSU data.

+ Unknown distribution of catch.

Reported catches have varied considerably between years, and the location of the catch in the late 1980s/early 1990s is uncertain, as some may have been taken from outside the EEZ, as well as misreported from other areas. Research fishing carried out under Special Permit in 1994 and 1995 resulted in catches of 45.2 t and 200.7 t, respectively (not included in Table 1).

ORANGE ROUGHY (ORH 1)

Based on an evaluation of the results of an Adaptive Management Programme (AMP) for the Mercury-Colville box initiated in 1995, the AMP was concluded and the TACC was reduced to 800 t for the 2000–01 fishing year. Catch limits of 200 t were established in each of four areas in ORH 1, with an individual seamount feature limit of 100 t. From 1 October 2001, ORH 1 was reintroduced into the AMP with different design parameters for the five years, and the TACC was increased from 800 to 1400 t and allocated an allowance of 70 t for other mortality caused by fishing. The AMP was discontinued in 2007.

In recent years the fishery has also developed off the west coast and sizeable catches have been taken off the Tauroa Knoll and West Norfolk Ridge.

Figure 1: Historical landings and TACC for ORH 1 (Auckland East). Note that this figure does not show data prior to entry into the QMS.

1.2 Recreational fisheries

There is no known non-commercial fishery for orange roughy in this area.

1.3 Customary non-commercial fisheries

No customary non-commercial fishing for orange roughy is known in this area.

1.4 Illegal catch

No quantitative information is available on the level of illegal catch in this area.

1.5 Other sources mortality

There may be some overrun of reported catch because of fish loss with trawl gear damage and ripped nets. In other orange roughy fisheries, a level of 5% has been estimated.

2. STOCKS AND AREAS

Orange roughy are distributed throughout the area. Spawning is known from several hills in the western Bay of Plenty as well as from features in the western regions of ORH 1. Stock status/affinities within the QMA are unknown. The Mercury-Colville grounds in the Bay of Plenty are about 120 n. miles from fishing grounds at East Cape (ORH 2A North), and spawning occurs at a similar time. Hence, it is likely that these are separate stocks. The Mercury and Colville Knolls in the Bay of Plenty are about 25 miles apart and may form a single stock. Stock affinities with other fishing hills in the southern and central Bay of Plenty are unknown. The Tauroa Knoll and outer Colville Ridge seamounts are distant from other commercial grounds, and these fish may also represent separate stocks.

3. STOCK ASSESSMENT

An assessment for the Mercury-Colville box was carried out in 2001 and is repeated here. A deterministic stock reduction technique (*after* Francis 1990) was used to estimate virgin biomass (B_0) and current biomass ($B_{current}$) for the Mercury-Colville orange roughy stock. The model was fitted to the biomass indices using maximum likelihood and assuming normal errors. In common with other orange roughy assessments, the maximum exploitation rate was set at 0.67. The model treats sexes separately, and assumes a Beverton-Holt stock-recruit relationship. Confidence intervals of the biomass estimates were derived from bootstrap analysis (Cordue & Francis 1994).

3.1 Estimates of fishery parameters and abundance

A series of trawl surveys of the Mercury-Colville box to estimate relative abundance were agreed under an Adaptive Management Programme. The first survey was carried out in June 1995 with a second survey in winter 1998 (Table 2). The biomass index of the latter survey was much lower than 1995, and because of warmer water temperatures it was uncertain whether the 1998 results were directly comparable to the 1995 results. They were not incorporated in the decision rule for the adaptive management programme. A third survey was carried out in June 2000, with the results suggesting that the abundance of orange roughy in the box had decreased considerably and was at low levels. However, these estimates are uncertain because of the suggestion that environmental factors may have influenced the distribution of orange roughy. The abundance indices from trawl survey and commercial catch-effort data used in the assessment are given in Table 2. The trawl survey indices had CVs of 0.27, 0.39 and 0.29 for 1995, 1998, and 2000 respectively.

Table 2: Biomass indices and reported catch used in estimation of B_0 . Values in square brackets are included for completeness; they are not used in the assessment.

Year	1993–94	1994–95	1995–96	1996–97	1997–98	1998–99	1999–00
Trawl survey	-	76 200	-	-	[2 500]	-	3 800
CPUE	8.3	9.1	5.4	4.2	[0.5]	1.5	(2.0)
Catch (t)	230	440	915	895	295	140	250

The CPUE series is mean catch per tow (sum of catches divided by number of tows, target ORH) from Mercury Knoll in the month of June. This is the only month when adequate data exist from the fishery to compare over time. A CV of 0.30 was assigned to the CPUE data.

Catch history information is derived from TCEPR records, scaled to the reported total catch for ORH 1. Overrun of reported catch (e.g., burst bags, inappropriate conversion factors) was assumed to be zero, as even if there was some, it is likely that it was similar between years. The catch in 1999–00 was assumed to be 250 t.

Assessments were carried out for three alternative sets of biomass indices (Table 3).

Table 3: Three alternative sets of biomass indices used in the stock assessment.

Alternative	Trawl survey indices	CPUE indices
1	1995, 2000	All except 1998
2	1995, 2000	None
3	1995, 2000	All except 1998 and 2000

Biological parameters used are those for the Chatham Rise stock, except for specific Bay of Plenty values for the maturity and recruitment ogives (Annala et al 2000).

3.2 Biomass estimates

The estimated virgin biomass (B_0) is very similar for all three alternative assessments (Table 4). With alternative 1 the estimated B_0 is 3200 t, with a current biomass of 15% B_0 . For both alternatives 2 and 3, the estimated B_0 is 3000 t, which is B_{min} , the minimum stock size which enables the catch history to be taken given a maximum exploitation rate of 0.67.

ORANGE ROUGHY (ORH 1)

Table 4: Biomass estimates (with 95% confidence intervals in parentheses) for stock assessments with the three alternatives of Table 3. B_0 is virgin biomass; B_{MSY} is interpreted as B_{MAY} , which is 30% B_0 ; $B_{current}$ is mid-season 1999–00; and B_{beg} is the biomass at the beginning of the 2000–01 fishing year. Estimates are rounded to the nearest 100 t (for B_0), 10 t (for other biomasses), or 1%.

Biomass	Alternative 1		Alternative 2		Alternative 3	
B_0 (t)	3 200	(3 000, 3 600)	3 000	(3 000, 3 500)	3 000	(3 000, 3 300)
B_{MSY} (t)	960	(900, 1080)	900	(900, 1050)	900	(900, 990)
$B_{current}$ (t)	490	(290, 890)	290	(290, 790)	290	(290, 590)
$B_{current}$ (% B_0)	15	(10, 25)	10	(10, 23)	10	(10, 18)
B_{beg} (t)	480	(270, 900)	270	(270, 800)	270	(270, 590)

The model fits the CPUE data reasonably well but estimates a smaller decline than is implied by the two trawl survey indices.

3.3 Yield estimates and projections

Yield estimates were determined using the simulation method described by Francis (1992) and the relative estimates of MCY , E_{CAY} and MAY , as given by Annala et al (2000).

Yield estimates are all much lower than recent catches (Table 5). Estimates of current yields ($MCY_{current}$ and CAY) lie between 16 t and 35 t; long-term yields ($MCY_{long-term}$ and MAY) lie between 44 t and 67 t.

Table 5: Yield estimates (t) for stock assessments with the three alternatives of Table 3.

Yield	Alternative 1		Alternative 2		Alternative 3	
$MCY_{current}$	35	(22, 53)	22	(22, 51)	22	(22, 44)
$MCY_{long-term}$	47	(44, 53)	44	(44, 51)	44	(44, 49)
CAY	29	(16, 54)	16	(16, 48)	16	(16, 36)
MAY	67	(58, 70)	58	(58, 68)	58	(58, 64)

CSP for this stock is just under 100 t for any B_0 between 3000 t and 3600 t.

4. ANALYSIS OF ADAPTIVE MANAGEMENT PROGRAMME

The ORH 1 TACC was increased from 800 to 1400 t in October 2001/02 under the Adaptive Management Programme. The objectives of this AMP were to determine stock size, geographical extent, and long-term sustainable yield of the ORH 1 stock. This is a complex AMP, with ORH 1 divided into four sub-areas (see Figure 2), each with total catch and “feature” catch limits (Table 6) (a “feature” was defined as being within a 10 n. mile radius of the shallowest point).

Table 6: Description of control rules implemented in the ORH 1 AMP.

ORH 1 Subarea	Proposed Catch Limit	Feature Limit (t/fishing year)
Area A	200 t	100 t
Area B	500 t	150 t
Area C	500 t	150 t
Area D	200 t	75 t

Feature limits also serve as limits to the total catch in any area due to the limited number of available productive features. The Mercury-Colville “Box” (located within Area D) has been given a specific limit of 30 t per year to allow for the bycatch of orange roughy when fishing for black cardinalfish. The catch of orange roughy in the Mercury-Colville “Box” is included in the overall limit for Area D.

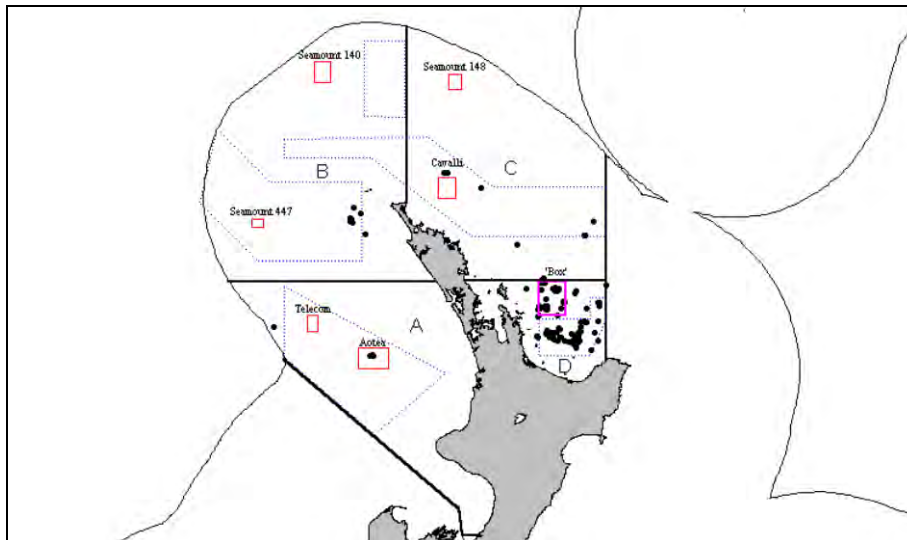

Figure 2: Four sub-management areas for the ORH 1 AMP (labelled A-D). Dotted lines enclose the exploratory fishing areas defined in the special permit issued on 6 July 1998. Solid lines enclose seamount closures and the Mercury-Colville Ohena ‘box’ (labelled at their top). Trawls (dots) where orange roughy were reported as the target species and caught during 1997–98 and 1998–99 are shown. Note that the lines separating Areas A and D from Areas B and C are incorrectly drawn at 36° S latitude rather than 35°30’ S latitude.

From 1 October 2007 the stock is no longer part of the Adaptive Management Programme but stakeholders have agreed to continue with the sub-area and feature limits within the overall ORH 1 TACC.

Review of ORH 1 AMP in 2007

In 2007 the AMP FAWG reviewed the performance of the AMP after the full 5-year term.

Fishery Characterisation

- In most years, the total catch has been less than the TACC (Table 7).
- The area splits into A, B, C and D only occurred in 2001.
- Main fishery is in area B; the fishery in area A only began in 2002.
- Two main goals of the AMP:
 - Reduce fishing in area D, in particular the Mercury-Colville “box”.
 - Look for new fishing areas, distributing effort across the QMA, with feature limits to reduce the possibility of localised overfishing.

Table 7: Estimated target catches by sub-area, scaled to landings, reported landings, and TACC for ORH 1. The scaling factor is calculated as reported catch/estimated (all target) catch (source: Anderson 2007b)

	Sub-area target catch (t)				Total target catch(t)	Reported landings (t)	TACC (t)	Scaling factor
	A	B	C	D				
1998	0.5	5.6	0.0	491.0	497	511	1 190	0.99
1999	5.2	575.2	165.0	724.5	1 470	1 543	1 190	0.99
2000	0.8	644.6	164.8	597.5	1 408	1 476	1 190	1.03
2001	8.5	166.3	99.4	164.6	439	858	800	1.11
2002	122.7	440.5	265.8	227.1	1 056	1 294	1 400	1.06
2003	196.7	508.1	237.9	72.2	1 015	1 123	1 400	0.98
2004	223.2	421.7	117.0	110.1	872	986	1 400	1.01
2005	277.0	389.8	173.4	174.1	1 014	1 151	1 400	1.13
2006	151.0	473.2	372.6	186.0	1 183	1 201	1 400	1.13

CPUE Analysis

- Unstandardised CPUE is in kg/tow. The short time series, the nature of the fishery (fishing aggregations spread over a wide area in different seasons) and the impact of catch limits on features

ORANGE ROUGHY (ORH 1)

and sub-areas prevent any useful relative abundance indices from being developed at this point for ORH 1.

- Where features are less than 10 n. mile apart, catch is apportioned according to the distance to the feature. Industry in-season reporting is based on the feature closest to the start of the tow.
- Possible problems with the area A observations in 2005–06, as there seem to be more reported tows than expected given the number of vessels operating in the area.

Observer Programme

- 50% observer coverage prior to 1 October 2006 (a high level relative to that for other deepwater stocks, with a large number of samples taken relative to the size of the fishery). From 1 October 2006, 100% coverage was requested by the Minister, but this has not been fully achieved, as some ORH 1 is taken as bycatch on trips that do not predominantly target ORH.
- The size frequency data show high levels of stock variability between fisheries on features or feature groups. Size variation does not seem to be linked to exploitation rate.

Environmental Effects

- Observer data from 2000 to 2003 indicated that incidental captures of seabirds did not occur in the ORH 1 target fishery (Baird 2005). Marine mammal interactions are also not a problem.
- Only three non-fish bycatch records have been reported from observed trips (in 1994 and 1995). All were shearwaters that landed on deck and were released alive. It was verified that observers were briefed in the same way as for other MFish trips including recording non-fish bycatch i.e. seabirds and marine mammals. Note that this does not include benthic organisms.
- The overall impact of bottom trawling on seamounts in ORH 1 is not known. A number of seamounts have been closed to fishing and the Norfolk Deep BPA is included in the industry accord relating to benthic protection areas within New Zealand's EEZ.

Sub-area D Directed Adaptive Exploratory Fishing Programme

- The purpose of this exercise was to establish whether fish populations shift between features in different years in sub-area D.
- Based on the results from the exploratory fishing from 2002 to 2005 it is evident that catches from all features contained a high proportion of ripe or ripe running females and that synchronised spawning occurs on a range of hills during winter.
- In 2006 the AMP Working Group recommended some changes to the design of the exploratory survey; however, this was not achieved during the 2006 survey.

The abbreviated checklist questions for full- and mid-term reviews are:

1. Is stock abundance adequately monitored?

The working group concluded that CPUE does not seem to be a proportional measure of abundance for this stock. However, CPUE is used in ORH 1 as a management tool. When CPUE drops on a feature, fishers are meant to move to another feature.

2. Is logbook coverage sufficient?

As there are Ministry fisheries observers on these vessels, fishers are not required to complete detailed logbooks for the AMP. This is the highest level of monitoring of any ORH fishery in New Zealand.

3. Are additional analyses of current data necessary?

No. The Working Group concluded that no other information can currently be extracted from the existing data that will provide insight into the status of the ORH 1 stocks. However, a potential problem with the 2005–06 catch records from Area A still needs to be checked.

4. Based on the biomass index, is current harvest sustainable?

Unknown. The purpose of the AMP was to spread effort in an attempt to reduce fishing pressure on any one sub-area or feature (and Area D in particular). ORH 1 is a large area, with orange roughy aggregations spread across a number of areas and features. The amount of fishing in some areas appears to be low, but without any indication of

current abundance, there is no way to determine if this level of fishing is in fact sustainable, or if current feature limits will avoid overexploitation of localised areas.

5. Where is stock, based on weight of evidence, in relation to B_{MSY} ?

Unknown. In 2001, when the AMP was initiated, the Working Group stated that the stock was likely to be above B_{MSY} ; while the information collected since that time has not improved the understanding about the status of the stock, the intent of the AMP design for ORH 1 was to spread effort to reduce the likelihood of the biomass declining below B_{MSY} .

ORH 1 is unlikely to be a single biological stock, and probably includes a number of constituent stocks. The Working Group concluded that it is not possible to estimate B_{MSY} for any of the individual stocks, let alone aggregate up to an estimate for ORH 1 as a whole. Moreover, a better understanding is not possible in the near future. B_{MSY} is difficult to estimate in situations involving an unknown number of constituent stocks.

6. Are the effects of fishing adequately monitored?

Yes, there is good observer coverage. The Working Group noted that one consequence of deliberately spreading effort was to increase the possible benthic impact.

7. Are rates of non-fish bycatch acceptable?

Yes.

8. Should the AMP be reviewed by the Plenary?

This AMP does not need to be reviewed by the Plenary.

5. STATUS OF THE STOCKS

From 1 October 2001, the TACC for ORH 1 was increased to 1400 t within the AMP, with sub-area and feature limits. From 1 October 2007 the stock is no longer part of the Adaptive Management Programme but stakeholders have agreed to continue with the sub-area and feature limits within the overall ORH 1 TACC.

In most years the total catch has been less than the TACC. However, it is not known if recent catch levels or current TACCs are sustainable in the long term. Except for the small area of the Mercury-Colville box no assessment of stock status is currently available.

An assessment of the Mercury-Colville box in 2001 indicated that biomass had been reduced to 10-15% B_0 (compared to an assumed B_{MSY} of 30% B_0). As the stock was considered to be well below B_{MSY} , a catch limit of 30 t was set for the box. The assessment indicated that a catch level of about 100 t would probably maintain the stock at the 2000 stock size (assuming deterministic recruitment) and catch levels from 16 to 35 t (consistent with *CAY* or *MCY* strategies) might allow the stock to rebuild slowly.

In other areas of ORH 1 the status of the constituent stocks is unknown. The amount of fishing in some areas appears to be low, but without any indication of current abundance, there is no way to determine if this level of fishing is in fact sustainable or if current feature limits will avoid overexploitation of localised areas.

ORANGE ROUGHY, CAPE RUNAWAY TO BANKS PENINSULA (ORH 2A, 2B, 3A)

1. FISHERY SUMMARY

1.1 Commercial fisheries

The first reported landings of orange roughy between Cape Runaway and Banks Peninsula were in 1981–82 occurring with the development of the Wairarapa fishery. Total reported catches and TACCs grouped into the three orange roughy Fishstocks from 1981–82 to 2012–13 are shown in Table 1. The historical catches and TACCs for these stocks are shown in Figure 1.

Table 1: Reported catches (t) and TACCs (t) from 1981–82 to 2012–13. QMS data from 1986–present.

* Ministry data † FSU data. § Included in QMA 3B TAC.

Includes shelving (an agreement that transfers ACE to a third party to effectively reduce the catch without adjusting the TACC)

There was a major change in the ORH 2A fishery in 1993–94 with a shift of effort from the main spawning hill on Ritchie Bank to hills off East Cape. Although these hills had apparently only been lightly fished in the past, during 1993–94 52% of the total catch from ORH 2A was taken from the East Cape area (Table 2). This led to an agreement between industry and the Minister responsible for fisheries that, from 1994–95, the traditionally fished areas within ORH 2A (south of 38°23', hereafter referred to as “2A South”) would be managed separately from the new East Cape fishery (north of 38°23', “2A North”). ORH 2A South was combined with ORH 2B and ORH 3A to form the Mid-East Coast (MEC) stock for management purposes.

The catch limits for these two areas changed three times in the following four years, including a subdivision of 2A North (Table 3). Catches in the exploratory sub-area of 2A North never approached the catch limit, with only 37 t being caught in 1996–97 and less in subsequent years.

ORANGE ROUGHY (ORH 2A, 2B, 3A)

Figure 1: Historical landings and TACCs for ORH 2A (Central (Gisborne)), ORH 2B (Central (Wairarapa)), and ORH 3A (Central/Challenger/South-East (Cook Strait/Kaikoura)). Note that these figures do not show data prior to entry into the QMS.

For the 2000–01 fishing year, the TACC for ORH 2A was reduced to 1100 t, that for ORH 2B to 185 t, and that for ORH 3A to 415 t. Within the TACC for ORH 2A, the catch limit for all of 2A North was reduced to 200 t, without specifying separate catch limits for the East Cape Hills and the exploratory area, while the catch limit for 2A South was reduced to 900 t. This gave a catch limit for the MEC stock of 1500 t. The catch limit for MEC was reduced to 800 t (and ORH 2A South to 480 t) for the 2002–03 and 2003–04 fishing years. From 1 October 2004 there was an increase in the TACC to 1100 t, 185 t, and 415 t in 2A, 2B, and 3A respectively. Furthermore, an allowance of 58 t, 9 t, and 21 t, for other mortality was allocated to 2A, 2B, and 3A in 2004 as well.

In 2012–13 the fishing industry voluntarily shelved (an agreement that transfers ACE to a third party to effectively reduce the catch without adjusting the TACC) approximately 25% of the MEC quota, resulting in effective catch limits of 510 t, 106 t, and 314 t for 2A South, 2B, and 3A respectively.

1.2 Recreational fisheries

Recreational fishing for orange roughy is not known in this area.

1.3 Customary non-commercial fisheries

No information on customary non-commercial fishing for orange roughy is available for this area.

1.4 Illegal catch

No information is available about illegal catch in this area.

Table 2: North Mid-East Coast + East Cape (ORH 2A) catches by area, in tonnes and by percentage of the total ORH 2A catch. (Percentages up to 1993–94 and from 2007–08 calculated from Ministry data; 1994–95 to 1996–97 from NZFIB data, and 1997–98 to 2006–07 from Orange Roughy Management Co.) Mid-East Coast (MEC) stock (ORH 2A South, ORH 2B, and ORH 3A combined) catches in tonnes.

*Catch limit for East Cape Hills including 500 t for the exploratory area.

1.5 Other sources of mortality

There has been a history of catch overruns in this area because of lost fish and discards, particularly in the early years of the fishery. In the assessments presented here total removals were assumed to exceed reported catches by the overrun percentages in Table 4.

All yield estimates and forward projections presented make an allowance for the current estimated level of overrun of 5%.

Table 4: Catch overruns (%) by QMA and year. -, no catches reported.

2. BIOLOGY

Biological parameters used in this assessment are presented in the Biology section at the beginning of the Orange Roughy Introduction section.

3. STOCKS AND AREAS

Two major spawning locations have been identified in ORH 2A, one at the East Cape Hills in “2A North” and the other on the Ritchie Bank in “2A South”. Spawning orange roughy were located in Wairarapa (ORH 2B) in winter 2001, but no large concentrations were found, and the significance of this spawning event is not known. Spawning orange roughy have not been located in Kaikoura (ORH 3A). The major spawning area in ORH 2A South, ORH 2B, and ORH 3A is still believed to be the Ritchie Bank, although spawning aggregations were not seen here in the 2013 AOS survey.

Results from allozyme studies showed that orange roughy from the three areas, “2A South”, Wairarapa, and Kaikoura could not be separated, but were distinct from fish on the eastern Chatham Rise. Earlier analyses that suggested there was a genetic stock boundary between East Cape and Ritchie Bank were not supported by a more recent replicate sample from East Cape. For these reasons, orange roughy in this region are currently treated as two stocks: the Mid-East Coast (MEC) stock (2A South, Wairarapa, and Kaikoura) and the East Cape (EC) stock (2A North). The relationship between these areas and the location of the main fishing grounds is shown in Figure 2.

4. STOCK ASSESSMENT

Stock assessments are reported below for East Cape from 2003 and for Mid East Coast (MEC) from 2014.

4.1 East Cape stock (2A North)

The stock assessment for the East Cape was last updated in 2003 and is summarised here (Anderson 2003b). An attempt to update the assessment with a new set of CPUE indices was made in 2006, but was rejected by the Working Group because of changes in the fishery which invalidated the utility of the CPUE series as an index of abundance. With no other abundance estimates available, an updated stock assessment was not possible.

4.1.1 Assessment Inputs

A CPUE analysis was performed in 2006, but was considered unreliable because of a change in fishing patterns and fleet size corresponding to the reduction of the catch limit to 200 t in 2000–01. The CPUE analysis was updated in 2011 and was considered more reliable by the Working Group due to the increase in the number of trawls per year since 2006. The 2011 analysis showed that standardised CPUE decreased after a peak in 2003–04, and has subsequently remained at a level similar to that in the late 1990s to early 2000s (Table 5).

Previous concerns by the Working Group that the fishery was dominated by a single vessel were alleviated somewhat by the return or entry of three other vessels to the fishery since 2003–04, but the utility of CPUE analyses in fisheries where substantial catch limit reductions have caused major changes in fishing patterns remains an issue for this stock.

The model inputs for the 2003 stock assessment were catches, an egg survey, and CPUE indices (Table 5). The biological parameters used are presented in the Biology section at the beginning of the Orange Roughy section.

ORANGE ROUGHY (ORH 2A, 2B, 3A)

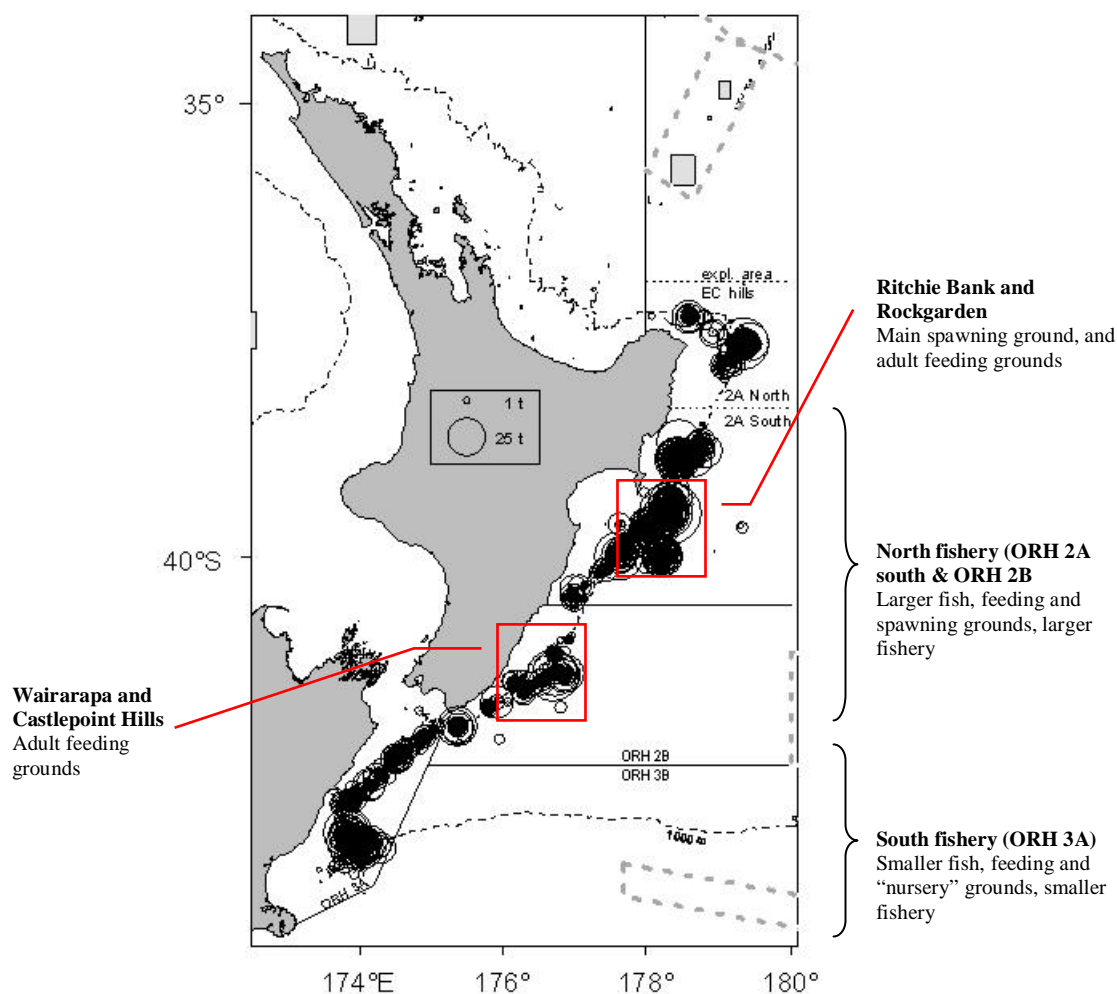

Figure 2: Catch (t) per tow of orange roughy in ORH 2A, ORH 2B, and ORH 3A for the five fishing years from 2006–07 to 2010–11 (circles, with area proportional to catch size), location of the fisheries assumed during stock assessment, and the location of the main spawning, feeding, and nursery grounds. Perimeters of Benthic Protection Areas (BPAs) closed to bottom trawling are marked with dashed grey lines, and seamounts closed to trawling are marked as shaded rectangles.

Table 5: Standardised CPUE and egg survey indices, and CVs for the East Cape stock, as used in the 2003 assessment, and an updated standardised CPUE index derived in 2011. -, no data.

	CPUE index 2003	CV(%)	Egg survey	CV(%)	CPUE index 2011	CV(%)
1993–94	1.00	12	-	-	0.95	23
1994–95	0.69	8	29 000	69	0.76	22
1995–96	0.60	8	-	-	0.61	23
1996–97	0.41	8	-	-	0.47	22

2005–06	-	-	-	-	0.37	28
2006–07	-	-	-	-	0.36	29
2007–08	-	-	-	-	0.27	28
2008–09	-	-	-	-	0.24	28
2009–10	-	-	-	-	0.20	27

4.1.2 Stock assessment

A stock assessment analysis for the East Cape stock was performed in 2003 using the stock assessment program, CASAL (Bull et al 2002) to estimate virgin and current biomass.

- The model was fitted using Bayesian estimation and partitioned the EC stock population by sex, maturity (the fishery was assumed to act on mature fish only) and age (age-groups used were 1–70, with a plus group).
- The model estimated virgin biomass, B_0 , and the process error for the CPUE indices. Catchability, q , was treated as a nuisance parameter by the model.
- The stock was considered to reside in a single area, and to have a single maturation episode modelled by a logistic-producing ogive where 50% of fish of both sexes were mature at age 26 and 95% at age 29.
- The catch equation used was the instantaneous mortality equation from Bull et al (2002) whereby half the natural mortality was applied, followed by the fishing mortality, then the remaining natural mortality.
- The size at age model used was the von Bertalanffy.
- No stock recruitment relationship was assumed.
- A Bayesian estimation procedure was used with a penalty function included to discourage the model from allowing the stock biomass to drop below a level at which the historical catch could not have been taken.
- Lognormal errors, with known (sampling error) CVs were assumed for the CPUE and egg survey indices. Additionally, process error variance was estimated by the model and added to the CVs from the CPUE indices.
- Confidence intervals were calculated from the posterior profile distribution of B_0 estimates, where the process error parameter was fixed at the value previously estimated.

4.1.3 Biomass estimates

Biomass estimates for this stock are given in Table 6 and the biomass trajectories, plotted against the scaled indices, are shown in Figure 3. The base case assessment of the EC stock included only the CPUE indices. An alternative assessment was carried out including the point estimate of biomass from the 1995 egg survey along with the CPUE indices. The CPUE indices agree well with the biomass estimates, with only the 1993–94 and 1997–98 indices departing from the biomass 95% confidence intervals. The egg survey biomass estimate, with the large associated CV, has little effect on the biomass trajectory.

Table 6: Estimates of virgin biomass (B_0), B_{MSY} (calculated as B_{MAY} , the mean biomass under a *CAY* policy), and B_{2003} , for the EC stock (with 95% confidence intervals in parentheses).

Assessment	Index	B_0 (t)	B_{MSY} (t)	B_{2003}		
				(t)	% B_0	(20–32)
Base case	CPUE	21 100 (19 650–23 350)	6 300	5 100	24	(20–32)
Alternative	CPUE + Egg survey	21 200 (19 700–23 550)	6 380	5 200	25	(20–33)

The base case estimate of $B_{CURRENT}$ (the mid-year biomass in 2002–03) is 5100 t (24% B_0) with a 95% confidence interval of 3800 to 7550 t. This is almost twice the value of B_{2003} estimated for mid-year 1999–2000 in the previous assessment (Anderson 2000). The alternative assessment gives a very similar estimate of B_{2003} .

Figure 3: Estimated biomass trajectories for the base case and alternative model runs for the EC stock. Annual biomass estimates are mean posterior density (MPD) values and 95% confidence intervals (grey dashed lines) are calculated from the posterior profile distribution of B_0 estimates. The CPUE index CVs (sampling error plus process error) are shown, as is the CV calculated for the egg survey biomass estimate.

4.1.4 Yield estimates and projections

Estimates of *MCY* and *CAY* for the EC stock were calculated from large numbers of simulation runs using posterior profile sampling of B_0 and a series of trial harvest levels. These estimates, together with *MAY* (the mean catch with a *CAY* harvesting strategy) and *CSP* (current surplus production) are given in Table 7. *CSP* is driven by recruitment of fish spawned before the fishery began.

Table 7: Estimates of *MCY*, *CAY*, *MAY*, and *CSP* for the EC stock, with 95% confidence intervals in parentheses (all corrected for an assumed overrun of 5%).

Assessment	<i>MCY</i> (t)	<i>CAY</i> (t)	<i>MAY</i> (t)	<i>CSP</i> (t)
Base case	350	370	410	550
Alternative	350	370	410	550

4.2 Mid-East Coast stock (2A South, 2B, 3A)

There was no new information available that would change the accepted stock definition of the MEC orange roughy stock i.e. comprising ORH 2A South, ORH 2B, and ORH 3A.

The Mid-East Coast (MEC) stock assessment was updated in 2014 using the methods common to the four assessments performed in 2014 (see Orange Roughy Introduction). The previous model based assessment was in 2013 but that assessment used data which did not meet the quality threshold applied in 2014 (i.e., CPUE indices, wide-area acoustic survey and egg-survey estimates). In 2014, an age-structured population model was fitted to the data described in section 4.2.2 below.

4.2.1 Model structure

The model was single-sex and age-structured (1-120 years with a plus group) with maturity in the partition (i.e., fish were classified by age and as mature or immature). A single area and a single time step were used with two year-round fisheries defined by different selectivities (a “southern” fishery catching young fish (double-normal selectivity) and a “northern” fishery catching older fish (logistic selectivity)). The spawning season was assumed to occur after 75% of the mortality and 100% of mature fish were assumed to spawn each year.

The catch history was constructed from the catches in Tables 1 & 2, adding the catch over-run percentages in Table 4. The northern fishery combined catches from ORH 2A South and ORH 2B, and the southern fishery used ORH 3A. Natural mortality was assumed to be fixed at 0.045 and the

stock-recruitment relationship was assumed to follow a Beverton-Holt function with steepness of 0.75. The remaining fixed biological parameters are given in the Orange Roughy Introduction.

4.2.2 Input data and statistical assumptions

There were three main data sources for observations fitted in the assessment: a spawning biomass estimate from an acoustic survey (2013); a trawl-survey time series of relative biomass indices (1992–1994, 2010) with associated length frequencies (1992, 1994), and age frequencies and estimates of proportion spawning at age (1993, 2010); and length and age frequencies collected from the commercial fisheries, including four spawning-season age frequencies (1989–1991, 2010).

Research surveys

The MEC area has been surveyed using acoustic and trawl methods, and egg surveys have also been conducted. Not all survey data have been used in the 2014 assessment. The egg survey estimates have some quality issues associated with them; the 1993 survey data were post-stratified and “corrected” for turn-over of fish (Zeldis et al 1997). The 1993 egg-survey estimate was used in the 2013 assessment but was not considered to be reliable enough for the 2014 assessment (which had a higher “quality threshold”). Similarly, the wide-area acoustic survey estimates from 2001 and 2003 (Doonan et al 2003, 2004a) were rejected in 2014 as being not sufficiently reliable (in particular, the biomass estimates primarily came from mixed species marks and “orange roughy” marks identified subjectively; rather than being from easily identified spawning plumes).

Trawl survey data

A time series of pre-spawning season, random, stratified, trawl surveys were conducted in March–April on *RV Tangaroa* in 1992–94 and 2010 (Grimes et al 1994, 1996a, 1996b; Doonan & Dunn 2011). The 2010 survey was specifically designed to be comparable with the earlier surveys and to produce an abundance index for the MEC home grounds (Doonan & Dunn 2011). In addition to the relative biomass indices (Table 8), the survey data were analysed to produce length frequencies from all years and age frequencies from 1993 and 2010 (Doonan et al 2011). Also, estimates of female proportion spawning at age were produced for the 1993 and 2010 surveys (Ian Doonan, pers. comm.).

Table 8: Biomass indices and CVs used in the stock assessment.

Year	Trawl index (t)	CV (%)	Acoustic index (t)	CV (%)
1992	20 838	29		
1993	15 102	27		
1994	12 780	14		
2010	7 074	19		
2011				
2012				
2013			4 225	20

The biomass indices were fitted as relative biomass with a double-normal selectivity (it is apparent that the trawl survey did not fully select the largest/oldest fish) and an uninformed prior on the proportionality constant (q). The length frequencies from 1992 and 1994 were fitted as multinomial, as were the age frequencies from 1993 and 2010 (length frequencies from 1993 and 2010 had been used in the production of the age frequencies). The proportion spawning at age was assumed binomial at each age. Effective sample sizes were all taken from the 2013 assessment (Cordue 2014).

Acoustic survey estimate

The only reliable acoustic estimate of spawning biomass for MEC came in 2013 when a multi-frequency “AOS” survey was conducted (acoustic and optical gear mounted on the trawl headline, e.g., see Kloser et al 2011). Four areas were visited in 2013 but the only substantial spawning plume was seen in the “Valley” (a known spawning site near Ritchie Bank). Four snapshots were taken and the estimates from 38 kHz were averaged to produce a biomass index (Table 8).

ORANGE ROUGHY (ORH 2A, 2B, 3A)

The “standard” assumption in the 2014 stock assessments, for acoustic estimates from spawning plumes, is that they collectively cover “most” of the spawning biomass where “most” is taken to be 80%. However, for MEC, only one spawning plume was found and it was in a very small area. There are many potential sites in the MEC for spawning plumes. For these reasons, “most” was taken to be 60% in the base model (and sensitivities were done at 40% and 80%). That is, the acoustic estimate was fitted as relative biomass with an informed prior: lognormal (mean = 0.6, CV = 19%) for the base model.

Commercial age and length frequencies

As in 2011 and 2013, composition data were also used: length frequency samples from the northern commercial fishery (ORH 2A South and ORH 2B) for 16 years between 1988–89 and 2009–10, and from the southern commercial fishery (ORH 3A) for nine years between 1989–90 and 2008–09, and age frequency samples from commercial landings of the spawning fishery in ORH 2A south in 1989, 1990, 1991. The otoliths from the 1989–91 samples were re-aged for the 2013 assessment using the new ageing protocol (Tracey et al 2007). In addition, age samples taken from a single vessel in the 2010 spawning season were also used. These had been aged with the new protocol but because they were from a single vessel and a fishery 20 years later than in 1990 the age frequency was fitted with its own selectivity. The age frequencies from 1989-91 were assumed to be from spawning fish (i.e., no selectivity fitted). The composition data were all assumed to be multinomial and effective samples sizes from the 2013 assessment were used (except the southern fishery length frequencies were down-weighted following the iterative reweighting procedure of Francis (2011)).

4.2.3 Model runs and results

In the base model, natural mortality (M) was fixed at 0.045. There were numerous MPD sensitivity runs and six main sensitivities are presented in this report: estimate M ; down-weight the trawl indices; separate selectivity for spawning age frequencies; mean acoustics q prior = 0.4; and the LowM-Highq and HighM-Lowq “standard” runs (see Orange Roughy Introduction).

In the base model, the main parameters estimated were: virgin biomass (B_0), the maturity ogive, the two fishery selectivities, the trawl survey selectivity, the 2010 age frequency selectivity, and year class strengths (YCS) from 1881 to 1996 (with the Haist parameterisation and “nearly uniform” priors on the free parameters). Additional estimated parameters included the CV of the length-at-age parameters and the proportionality constants (qs) for the trawl survey time series and the 2013 acoustics estimate.

Model diagnostics

The MPD fits to the biomass indices were excellent (Figure 4), although the MCMC fit was only just adequate for the trawl survey indices, particularly to the 2010 index (Figure 5). The poorer MCMC fit to the 2010 trawl index when compared to the MPD fit occurred because the MPD pattern of YCS did not match the posterior distribution of the same quantities, showing much greater year-to-year variation than seen in the MCMC posterior (Figure 6). This result highlights the difference between MPD estimates and MCMC estimates: the MPD finds the single vector of parameters which give the best fit to the data, while the MCMC procedure finds the parameter space that best explains the data. There is no reason why the MPD has to be in the “middle” of the posterior distribution, here we have an example where the MPD estimates are in the tail of the posterior distribution.

The MCMC fit to the acoustics index had also degraded when compared to the MPD fit (see Figures 4 and 5), as well as estimating a lower acoustics q (Figure 7). The cause of this is the same as for the 2010 trawl index; the MPD spawning biomass trajectory almost exactly matched the 2013 acoustic estimate but, given the less variable MCMC YCS trajectory, the resulting MCMC biomass trajectory was shifted higher (and the acoustic q shifted lower to compensate).

Figure 4: MPD fit to biomass indices: left: acoustic-survey spawning biomass index (fitted with an informed q prior, mean = 0.6; MPD estimated $q = 0.59$); right: *Tangaroa* trawl-survey indices. Vertical lines are 95% CIs.

Figure 5: MCMC base: normalised residuals for the biomass indices. The box covers 50% of the distribution for each index and the whiskers extend to 95% of the distribution. “Aco” denotes the acoustic estimate (2013). “Trawl” denotes the *Tangaroa* trawl-survey time series (1992-94, 2010).

ORANGE ROUGHY (ORH 2A, 2B, 3A)

Figure 6: Base model: MCMC estimated “true” YCS (R_y/R_0) (in black). The box in each year covers 50% of the distribution and the whiskers extend to 95% of the distribution. The MPD estimates are shown in red.

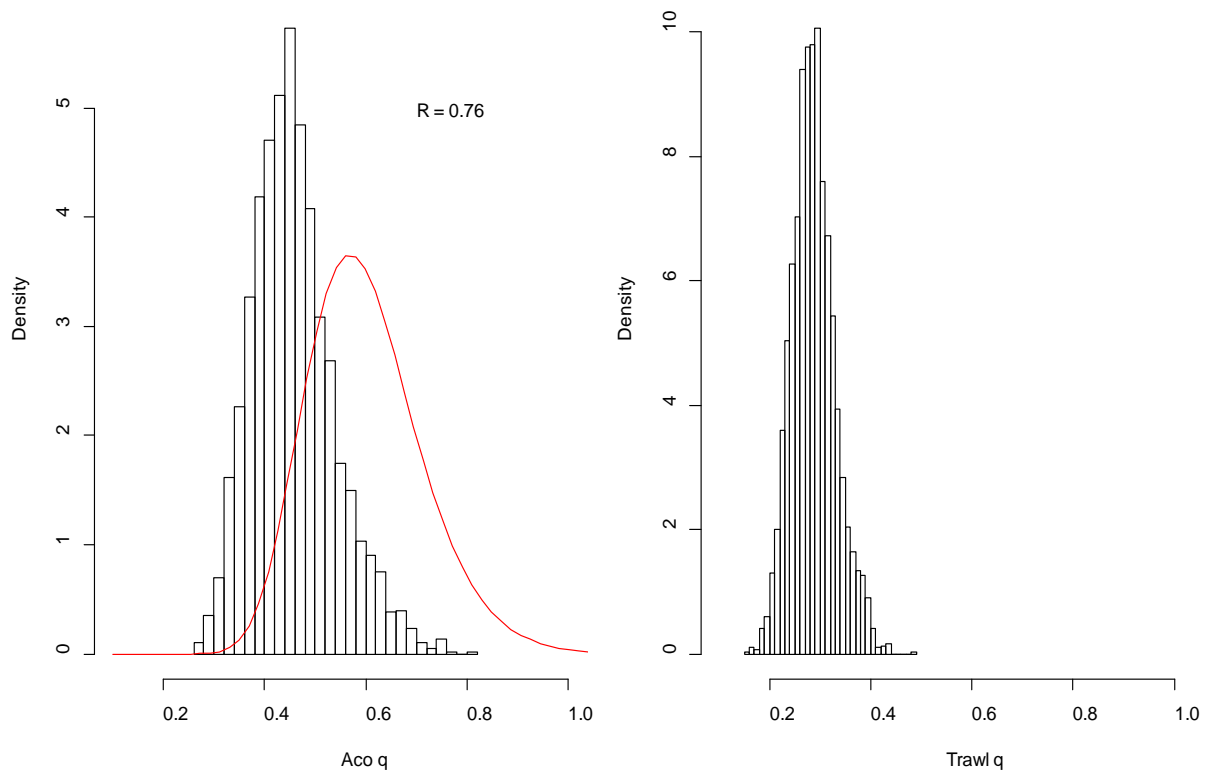

Figure 7: Base model MCMC diagnostics: prior and posterior distributions for the acoustic q (prior in red, posterior black histogram) (left); posterior distribution for the trawl-survey q (the prior was uninformed) (right). $R = 0.76$ is the ratio of the mean of the acoustic q posterior to the mean of the prior.

The MPD fits to the commercial length frequencies were adequate (Figures 8 and 9). They could never be very good because the length frequencies show a great deal of year-to-year variability, as evidenced by the annual mean lengths (Figure 10). The model predictions of annual mean length are necessarily fairly smooth from year-to-year; as they are only able to track the main trend but not the annual jumps (Figure 10).

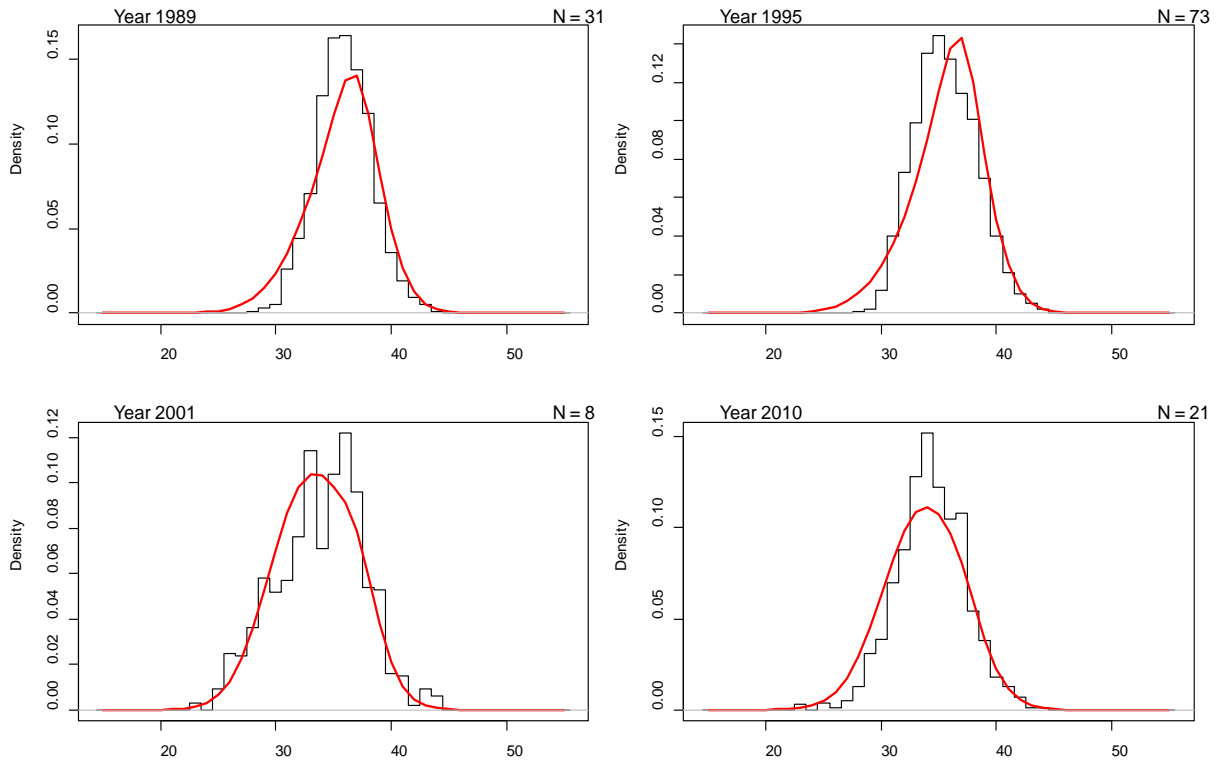

Figure 8: Example MPD fits to northern fishery length frequencies (N is the assumed effective sample size in the given year; x-axis is fish length (cm)). Observations are black lines; model predictions are the red lines.

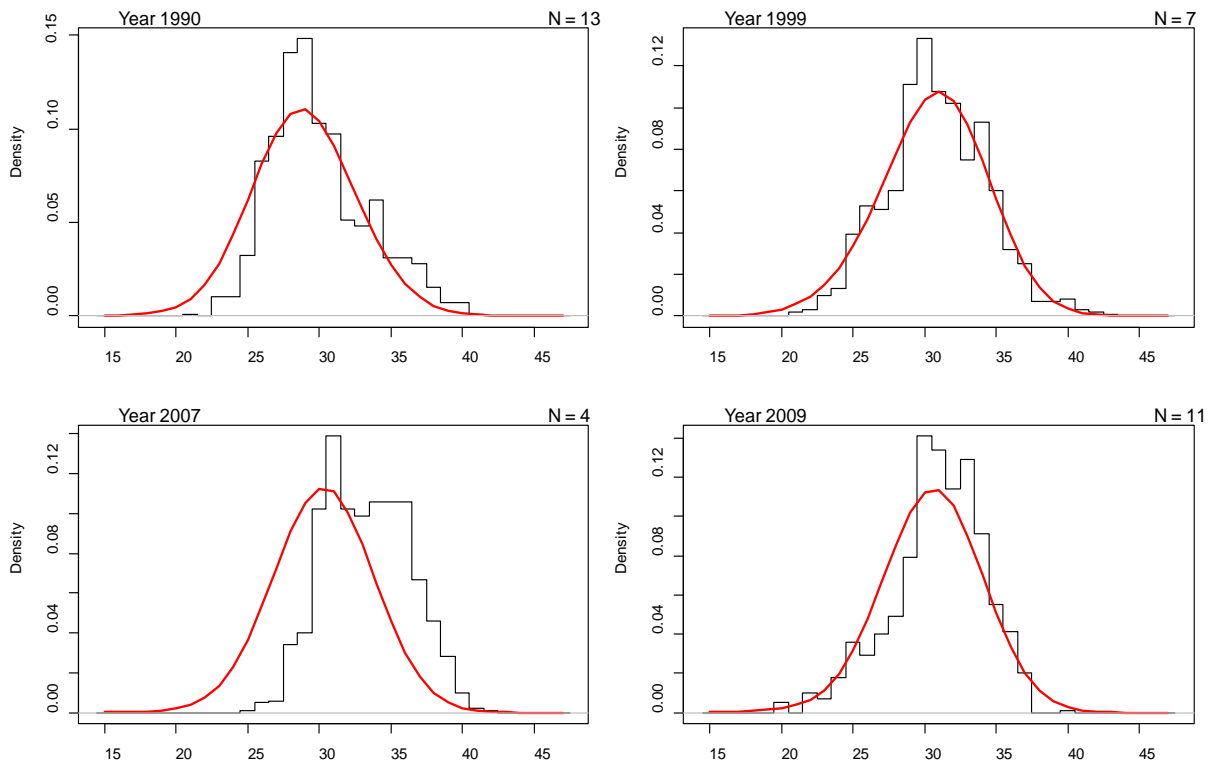

Figure 9: Example MPD fits to southern fishery length frequencies (N is the assumed effective sample size in the given year; x axis is fish length (cm)). Observations are black lines; model predictions are the red lines.

ORANGE ROUGHY (ORH 2A, 2B, 3A)

Figure 10: Annual mean lengths from the commercial length frequencies (northern fishery on the left, southern on the right) with 95% CIs (black, circles, dashed vertical lines) and the base model predictions (red, triangles, solid lines).

The MPD fits to the trawl-survey length frequencies and estimates of proportion spawning at age are good (Figure 11). It is notable that the model fits the different shape of the proportion spawning estimates in 1993 and 2010 (Figure 11). The spawning-season age frequencies are only adequately fitted (Figure 12). There is a misfit for the young ages (except for 2010 which had its own selectivity) as these data compete with the proportion spawning-at-age data to define the maturity ogive (see Figure 11 – young fish are spawning according to the proportion spawning data). In response to the misfit in Figure 12, a sensitivity run was done where the 1989-91 spawning age frequencies were allowed to have a logistic selectivity. This improved the fit substantially and raised the model estimate of the 2014 stock status from 14 to 17% B_0 . The base model was preferred to be consistent across the four orange roughy stocks assessed in 2014, with the maturity ogive used to define the spawning-season selectivity and age frequencies.

The fit to the trawl-survey age frequencies is excellent, which should be expected given the large effective sample size of $N = 200$ (Figure 13). A number of sensitivity runs were done with alternative data weighting, including down-weighting the trawl-survey age frequencies, which demonstrated that the model was robust to a wide range of assumptions. For example, the only runs that made a substantial difference to the MPD estimates of stock status were doubling the acoustic index (10.2% B_0 compared to the base estimate of 6.5% B_0) and assuming deterministic recruitment (25.8% B_0); the other 16 runs had MPD estimates in the range 4–9% B_0 .

ORANGE ROUGHY (ORH 2A, 2B, 3A)

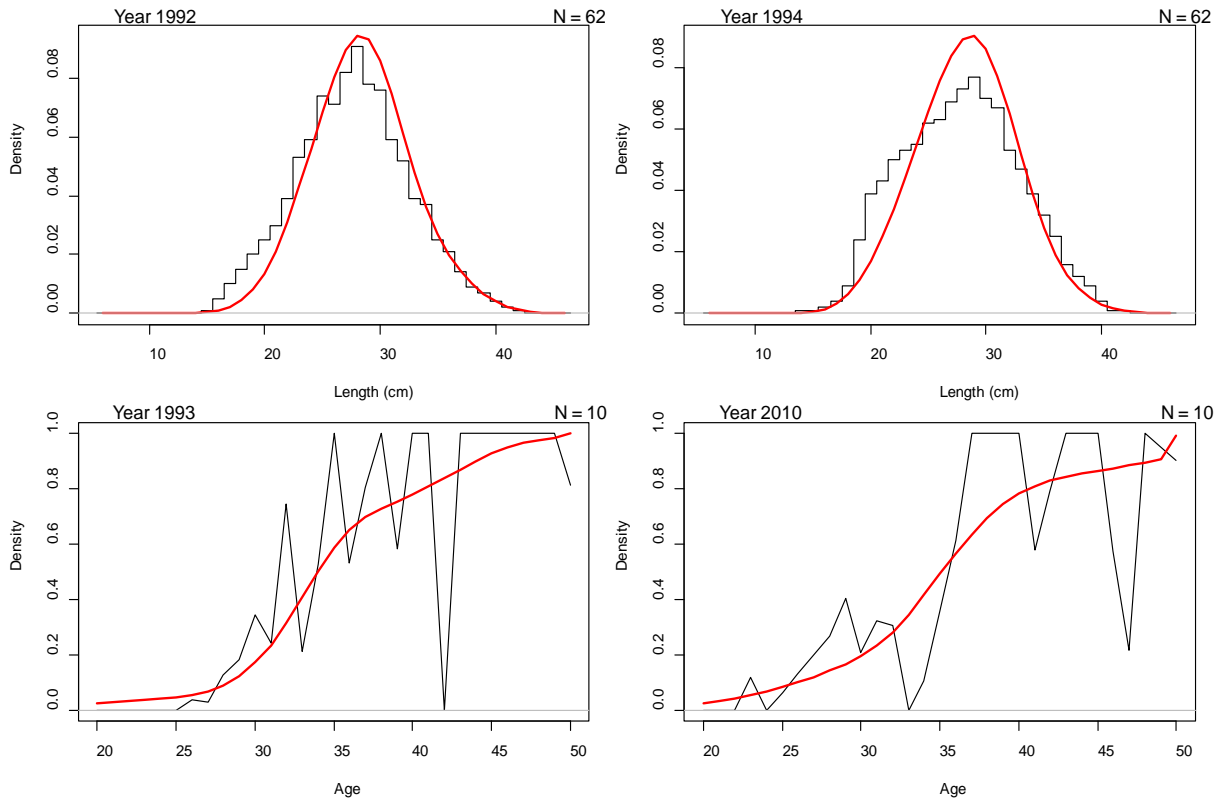

Figure 11: Base, MPD fits to trawl-survey length frequencies (N is the assumed effective sample size in the given year) and proportion spawning-at-age (N =10 is the binomial sample size assumed for each age). Observations are black lines; model predictions are the red lines.

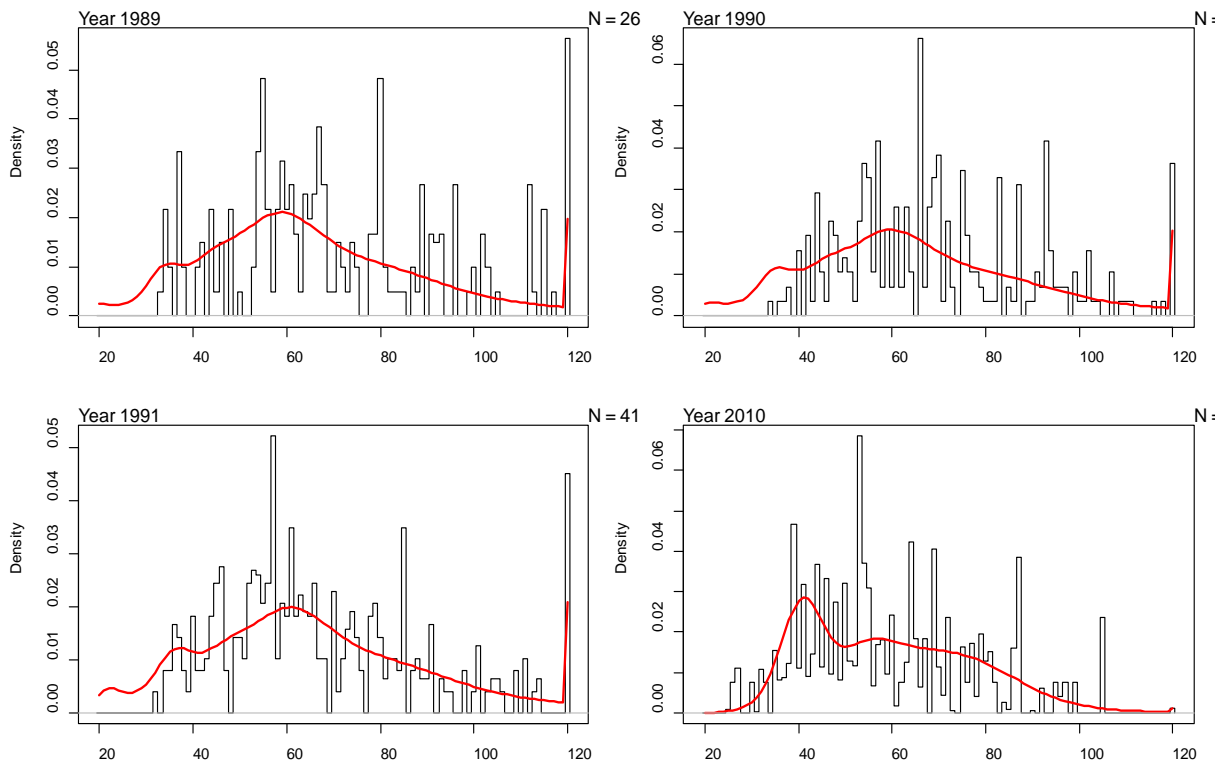

Figure 12: Base, MPD fit to spawning-season age frequencies (N is the assumed effective sample size in the given year). Observations are black lines; model predictions are the red lines.

ORANGE ROUGHY (ORH 2A, 2B, 3A)

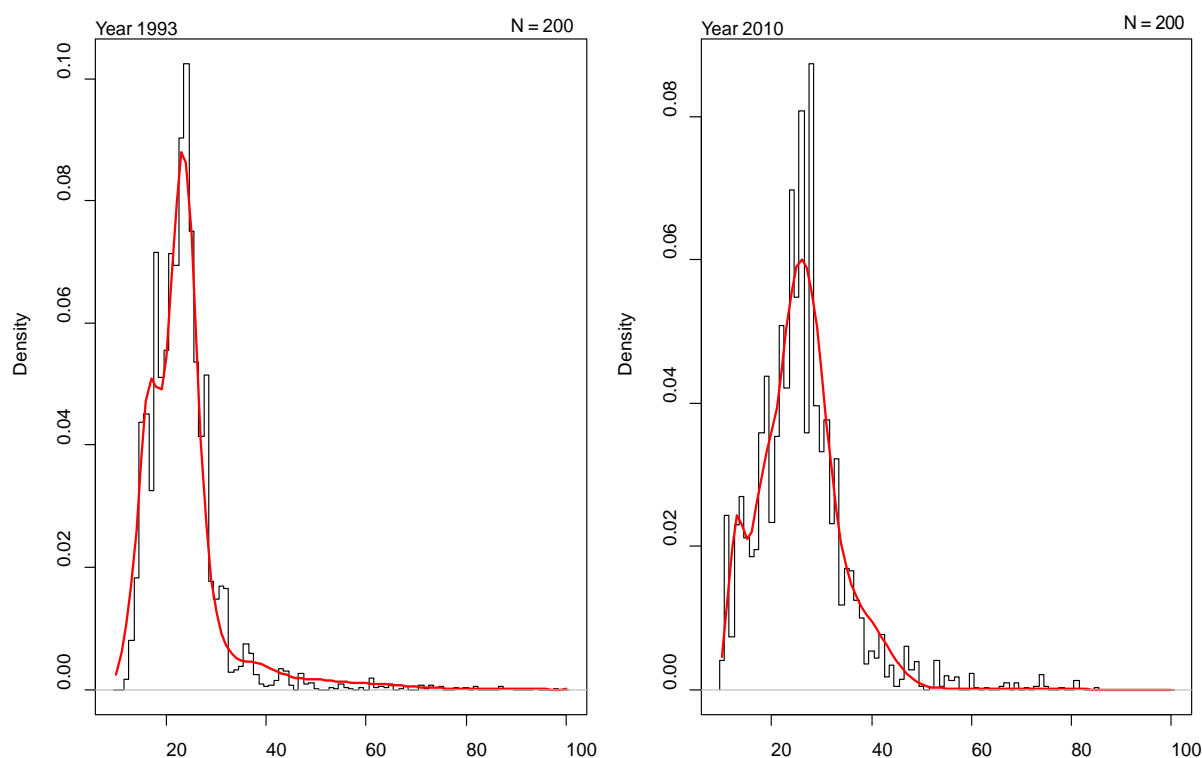

Figure 13: Base, MPD fit to trawl-survey age frequencies (N = 200 is the assumed effective sample size). Observations are black lines; model predictions are the red lines.

MCMC results

MCMC convergence diagnostics were very good for the base model and sensitivities. Virgin biomass (B_0) was estimated to be about 100,000 t for all runs (Table 9). Current stock status was similar for the base and the estimate- M run (Table 9). The slightly lower stock status when M was estimated reflects the lower estimate of M (0.032 rather than 0.045). Down-weighting the trawl indices (by adding process error CV of 20%) reduced the magnitude of the normalised residuals and raised the median estimate of 2014 stock status from 14 to 16% B_0 (Table 9). Giving the 1989–91 spawning age frequencies a selectivity improved the fit to younger age fish, decreased the estimate of B_0 from 95 000 t to 91 000 t and increased estimated stock status from 14 to 17% B_0 (Table 9). The reduction in the mean of the acoustic q from 0.6 to 0.4 increased the median estimate of stock status to 19% B_0 , but the median estimate was still below the soft limit (Table 9). The two “bounding runs” where M and the mean of the acoustic q were shifted by 20%, still had median estimates under the soft limit, with the “LowM-Highq” run at the hard limit (Table 9). Other sensitivities not reported here included several where the effective sample size on age frequencies was appreciably increased or decreased; in all cases, this had little impact on the estimates of stock status.

Table 9: MCMC estimates of virgin biomass (B_0) and stock status (B_{2014} as % B_0) for the base model, and the six following sensitivity runs: a) estimating natural mortality; b) down-weighting the trawl indices by adding 20% process error to the CV; c) adding a selectivity to spawning age frequencies for 1989–91; d) reducing the mean acoustic catchability coefficient, q , from 0.6 to 0.4; e) decreasing M and increasing acoustic q by 20%; and f) increasing M and decreasing acoustic q by 20%.

Assessment	M	B_0 (000 t)	95% CI	B_{2014} (% B_0)	95% CI
Base model	0.045	95	87–104	14	9–21
a) Estimate M	0.032	104	96–112	11	7–16
b) Down-weight trawl	0.045	97	88–108	16	11–22

e) LowM-Highq	0.036	96	90–103	10	7–15
f) HighM-Lowq	0.054	99	89–114	19	13–27

The estimated fishery selectivities showed the northern fishery taking fish over 30 years with the southern fishery primarily taking fish from 20–40 years (Figure 14). The trawl-survey selectivity primarily sampled fish from 10–70 years with peak selection from 20–30 years (Figure 14). The 2010

age frequency appears to have been a subset of spawning fish focussed on those from about 50-90 years (Figure 14).

Figure 14: Base, MCMC estimated selectivities (northern and southern fisheries, the trawl survey, and the 2010 age frequency). The box at each age covers 50% of the distribution and the whiskers extend to 95% of the distribution.

The estimated YCS show strong variation across cohorts and exhibit a long-term trend, with recruitment well below average since the early 1970s (Figure 15). The most recent 10 years of estimates, 1986–1995 (those resampled for short-term projections) are well below average.

Figure 15: Base, MCMC estimated “true” YCS (R_y/R_0). The box in each year covers 50% of the distribution and the whiskers extend to 95% of the distribution.

ORANGE ROUGHY (ORH 2A, 2B, 3A)

The stock status trajectory shows an increasing trend before the start of fishery as the above average recruitment estimated by the model feeds into the spawning biomass (Figure 16). Then there is a steep decline from the start of fishery until the year 2000 when the biomass reached 10% B_0 , after which there was a slow increase (Figure 16).

Figure 16: Base, MCMC estimated spawning-stock biomass trajectory. The box in each year covers 50% of the distribution and the whiskers extend to 95% of the distribution. The hard limit, 10% B_0 (red), soft limit, 20% B_0 (blue), and biomass target range, 30–40% B_0 (green) are marked by horizontal lines.

Fishing intensity was estimated in each year for each MCMC sample to produce a posterior distribution for fishing intensity in each year. Fishing intensity is represented in term of the median exploitation rate and the Equilibrium Stock Depletion (ESD). For the latter, a fishing intensity of $U_{x\%B_0}$ means that fishing (forever) at that intensity will cause the SSB to reach deterministic equilibrium at x% B_0 (e.g., fishing at $U_{30\%B_0}$ drives the SSB to a deterministic equilibrium of 30% B_0). Fishing intensity in these units is plotted as 100–ESD so that fishing intensity ranges from 0 ($U_{100\%B_0}$) up to 100 ($U_{0\%B_0}$).

Estimated fishing intensity was above the target range ($U_{30\%B_0}$ – $U_{40\%B_0}$) from 1984 to 2012 (Figure 17). In the last two years, fishing intensity has decreased to within the target range.

Figure 17: Base, MCMC estimated fishing-intensity trajectory. The box in each year covers 50% of the distribution and the whiskers extend to 95% of the distribution. The fishing-intensity range associated with the biomass target of 30-40% B_0 is marked by horizontal lines.

Biological reference points, management targets and yield

MCMC estimates of deterministic B_{MSY} and associated values were produced for the base model. The yield at 35% B_0 (the mid-point of the target range) was also estimated. There is little variation in the reference points and associated values across the MCMC samples (Table 10).

There are several reasons why deterministic B_{MSY} is not a suitable target for use in fisheries management. First, it assumes a harvest strategy that is unrealistic in that it involves perfect knowledge (current biomass must be known exactly in order to calculate the target catch) and annual changes in TACC (which are unlikely to happen in New Zealand and not desirable for most stakeholders). Second, it assumes perfect knowledge of the stock-recruit relationship, which is often poorly known. Third, it would be very difficult with such a low biomass target to avoid the biomass occasionally falling below 20% B_0 , the default soft limit according to the Harvest Strategy Standard.

Table 10: Base, MCMC estimates of deterministic equilibrium spawning stock biomass (SSB) and long-term yield (% B_0 and tonnes) for U_{MSY} and $U_{35\%B_0}$. The equilibrium SSB at U_{MSY} is deterministic B_{MSY} and the yield is deterministic MSY .

Fishing intensity		SSB (% B_0)	Yield (% B_0)	Yield (t)
U_{MSY}	Median	22.5	2.3	2214
	95% CI	21.8–23.0	2.3–2.4	2048–2415
$U_{35\%B_0}$	Median	35.0	2.2	2075
	95% CI	35.0–35.0	2.2–2.2	1916–2264

Projections

Five year projections were conducted (with resampling from the last 10 estimated YCS) for catch at the current catch limit of 930 t (with a 5% catch over-run assumed). Projections were done just for the base model.

ORANGE ROUGHY (ORH 2A, 2B, 3A)

At the current catch limit (930 t), SSB is predicted to increase slowly over the next five years but still be well below the soft limit in 2019 (Figure 18). The estimated minimum time to rebuild (assuming zero catch and requiring a 70% probability of being above the lower bound of the 30–40% B_0 target range), is 21 years (T_{min}) (Figure 19).

Figure 18: Base, MCMC projections. The box in each year covers 50% of the distribution and the whiskers extend to 95% of the distribution. An annual catch at the current catch limit of 930 t was assumed (with a 5% catch over-run in each year). The target range (30–40% B_0) is indicated by horizontal green lines, with the soft limit (20% B_0) in blue and the hard limit (10% B_0) in red.

Figure 19: Base, MCMC projections. The box in each year covers 50% of the distribution and the whiskers extend to 95% of the distribution. The annual catch used in these projections is zero tonnes. The target range (30–40% B_0) is indicated by horizontal green lines, with the soft limit (20% B_0) in blue and the hard limit (10% B_0) in red.

5. STATUS OF THE STOCKS

Stock Structure Assumptions

Orange roughy in ORH 2A, 2B and 3A are treated as two biological stocks based on the location of spawning grounds. These stocks are managed and assessed separately however some mixing has been shown to occur. The 2A North stock spawns around the East Cape hills off of the North Island. The 2A South, 2B and 3A stock is assumed to spawn on the Ritchie Bank.

For orange roughy stocks, the current management target is a biomass range from 30–40% B_0 .

• **ORH East Cape Stock (2A North)**

Stock Status	
Year of Most Recent Assessment	2003
Assessment Runs Presented	A base case with one alternative
Reference Points	Management Target: 30% B_0 Soft Limit: 20% B_0 Hard Limit: 10% B_0
Status in relation to Target	B_{2003} was 24% B_0 , which was Unlikely (< 40%) to be at or above the target
Status in relation to Limits	B_{2003} was Unlikely (< 40%) to be below the Soft Limit, and Very Unlikely (< 10%) to be below the Hard Limit

Historical Stock Status Trajectory and Current Status

Estimated biomass trajectory for the base model run for the EC stock. Annual biomass estimates are mean posterior density (MPD) values and 95% confidence intervals (grey dashed lines) are calculated from the posterior profile distribution of B_0 estimates. The CPUE index CVs (sampling error plus process error) are shown.

Fishery and Stock Trends	
Recent Trend in Biomass or Proxy	Biomass declined in the early 1990s but appeared to stabilise at around 5000 t.
Recent Trend in Fishing Mortality or Proxy	F has declined along with the agreed catch limit and remains stable at the current catch level of 200 t.
Other Abundance Indices	-
Trends in Other Relevant Indicators or Variables	-

ORANGE ROUGHY (ORH 2A, 2B, 3A)

Projections and Prognosis (2003)	
Stock Projections or Prognosis	The estimated <i>CAY</i> (370 t) and <i>MAY</i> (410 t) were both greater than the catch limit of 200 t, and this suggested the stock would start to rebuild.
Probability of Current Catch or TACC causing decline below Limits	Soft Limit: Unlikely (< 40%) Hard Limit: Very Unlikely (< 10%)

Assessment Methodology	
Assessment Type	Type 1 - Quantitative stock assessment
Assessment Method	Statistical catch-at-age model implemented in CASAL with Bayesian estimation of posterior distributions
Main data inputs	- Catch data - Standardised CPUE data - 1994–95 ORH egg survey
Period of Assessment	Latest assessment: 2003 Next assessment: Unknown
Changes to Model Structure and Assumptions	-
Major Sources of Uncertainty	-

Qualifying Comments
The most recent assessment (2003) is now 11 years out-of-date. In recent years, the ability of stock assessment models that assume deterministic recruitment for orange roughy stocks to reflect current or projected stock status has been called into question.

Fishery Interactions
The main bycatch species are cardinalfish and alfonsino. Low productivity bycatch species include deepwater sharks, deepsea skates and corals. Protected species bycatch includes seabirds and corals.

• **ORH Mid-East Coast Stock (2A South, 2B, 3A)**

Stock Status	
Year of Most Recent Assessment	2014
Assessment Runs Presented	Base model only
Reference Points	Management Target: Biomass range 30–40% B_0 Soft Limit: 20% B_0 Hard Limit: 10% B_0 Overfishing threshold: Fishing intensity range $U_{30\%B_0}$ – $U_{40\%B_0}$
Status in relation to Target	B_{2014} was estimated to be 14% B_0 Very Unlikely (< 10%) to be at or above the lower end of the management target range
Status in relation to Limits	B_{2014} is Likely (> 60%) to be below the Soft Limit B_{2014} is Unlikely (< 40%) to be below the Hard Limit
Status in relation to Overfishing	Fishing intensity in 2014 was estimated at $U_{35\%B_0}$ Overfishing is About as Likely as Not (40-60%) to be occurring

Historical Stock Status Trajectory and Current Status

Historical trajectory of spawning biomass ($%B_0$), median exploitation rate (%) and fishing intensity (100-ESD) (base model, medians of the marginal posteriors). The biomass target range of 30-40% B_0 and the corresponding exploitation rate (fishing intensity) range are marked in green. The soft limit (20% B_0) is marked in blue and the hard limit (10% B_0) in red. Note that the Y-axis is non-linear.

Fishery and Stock Trends

Recent Trend in Biomass or Proxy	Estimated spawning biomass has been slowly increasing since about 2000.
Recent Trend in Fishing Intensity or Proxy	Estimated fishing intensity has been declining in recent years.
Other Abundance Indices	-
Trends in Other Relevant Indicators or Variables	-

Projections and Prognosis

Stock Projections or Prognosis	At the current catch limit, the stock is projected to increase slowly over the next 5 years but still be below the soft limit in 2019. The minimum rebuild period to reach 30% B_0 with 70% probability is estimated to be 21 years with no catch.
Probability of Current Catch or TACC causing Biomass to remain below, or to decline below, Limits	For the current catch and catch limit (in the short term): Soft Limit: Very Likely (> 90%) Hard Limit: Unlikely (< 40%)
Probability of Current Catch or TACC causing Overfishing to continue or to commence	For the current catch and catch limit: As Likely as Not (40-60%)

Assessment Methodology and Evaluation

Assessment Type	Level 1 - Full quantitative stock assessment	
Assessment Method	Age-structured CASAL model with Bayesian estimation of posterior distributions	
Assessment Dates	Latest assessment: 2014	Next assessment: Unknown
Overall assessment quality rank	1 – High Quality	

ORANGE ROUGHY (ORH 2A, 2B, 3A)

Main data inputs (rank)	- Acoustic biomass estimate (2013) - Trawl-survey biomass indices (1992–94, 2010), age frequencies (1993, 2010), length frequencies (1992, 1994), proportion spawning at age (1993, 2010) - Spawning-season age frequencies (1989–91, 2010) - Commercial length-frequencies (1989–90 to 2009–10)	1 – High Quality 1 – High Quality 1 – High Quality 1 – High Quality
Data not used (rank)	- CPUE indices - 2002 spawning-season age frequency - Wide-area acoustic estimates - Egg survey estimates	3 – Low Quality (unlikely to be indexing stock-wide abundance) 2 – Mixed Quality (needs to be re-aged) 2 – Mixed Quality (too much potential bias due to target identification and mixed species issues) 2 – Mixed Quality (too much potential bias due to survey design assumptions not being met)
Changes to Model Structure and Assumptions	A more stringent data quality threshold was imposed on data inputs (e.g., wide-area acoustics, egg survey, and CPUE indices not used).	
Major Sources of Uncertainty	-The proportion of the spawning stock biomass that was indexed by the 2013 acoustic survey (little survey effort has been expended in this area relative to other orange roughy grounds). -Patterns in year class strengths are based on only 5 years of age composition data.	

Qualifying Comments

- Estimates of stock biomass are sensitive to the means of the q priors. In addition, when higher CVs were used for the informed acoustic q priors, the median estimates of biomass and stock status were slightly higher and the confidence intervals were wider with a much higher upper bound.

Fishery Interactions

Fish bycatch is estimated to make up about 20% of the total catch in this fishery. The main bycatch species are alfonsino, smooth oreo and hoki. Low productivity bycatch species include deepwater sharks, deepsea skates and corals. Observed incidental captures of protected species include corals and very small numbers of seabirds.

**ORANGE ROUGHY, CHATHAM RISE AND SOUTHERN
NEW ZEALAND (ORH 3B)**

1. FISHERY SUMMARY**1.1 Commercial fisheries**

Orange roughy are found in waters deeper than 750 m throughout Quota Management Area 3B. Historically, the main fishery has been concentrated on the Chatham Rise. Annual reported orange roughy catches in ORH 3B ranged between 24 000–33 000 t in the 1980s, progressively decreased from 1989–90 to 1995–96 because of a series of TACC reductions, were stable over the mid-1990s–mid-2000s and decreased further from 2005–2006 as TACCs were further reduced (Table 1 and Figure 1).

Table 1: Annual reported catches and TACCs of orange roughy from ORH 3B. (Catches from 1978–79 to 1985–86 are from Robertson & Mace 1988) and from 1986–87 to 2012–13 from Fisheries Statistics Unit and Quota Monitoring System data). ‡

Fishing year	Reported catch (t)	TACC (t)	Agreed catch limit (t) β

† Catches for 1979–80 to 1981–82 are for an April–March fishing year.

* Catches for 1982–83 and 1983–84 are 15 month totals to accommodate the change over from an April–March fishing year to an October–September fishing year. The TACC for the interim season, March to September 1983, was 16 125 t.

‡ Catches from 1984–85 onwards are for a 1 October–30 September fishing year.

β Agreed, non-regulatory catch limits between industry and MPI, which includes ‘shelving’ (an agreement that transfers ACE to a third party to effectively reduce the catch without adjusting the TACC).

There have been major changes in the distribution of catch and effort over the history of this fishery (Table 2). Initially, it was confined to the Chatham Rise and, until 1982, most of the catch was taken from areas of relatively flat bottom on the northern slopes of the Rise (in the Spawning Box), between mid-June and mid-August, when the fish form large aggregations for spawning (Figure 2).

From 1983 to 1989 about one third of the catch was taken from the south and east Chatham Rise, where new fishing grounds developed on and around knolls and hill features. Much of the catch from these areas was taken outside the spawning season as the fishery extended to most months of the year.

Figure 1: Historical landings and TACCs for ORH 3B. Note that this figure does not show data prior to entry into the QMS.

Table 2: ORH 3B catches by area, to the nearest 10 t or 100 t, and by percentage (to the nearest percent) of the total ORH 3B reported catch. Catches are equivalent to those shown in Table 1, but allocated to area using the ratio of estimated catches, and revised such that all years are from 1 October–30 September. Note that catches for the East Rise are given by the sum of Spawning Box and Rest of East Rise.

Year	Northwest Rise		South Rise		Spawning box		Rest of East Rise		Non-Chatham

ORANGE ROUGHY (ORH 3B)

In the early 1990s, effort within the Chatham Rise further shifted from the Spawning Box to eastern and northwestern parts of the Rise. The Spawning Box was closed to fishing from 1992–93 to 1994–95. In more recent years, catches from the main fishing grounds on the Chatham Rise have declined due to TACC reductions.

The early 1990s also saw the Puysegur fishery develop, followed by other fishing grounds near the Auckland Islands and on the Pukaki Rise, which was also a focus for the fishery south of the Chatham Rise.

Since 1992–93, the distribution of the catch within ORH 3B has been affected by a series of catch-limit agreements between the fishing industry and the Minister responsible for fisheries. Initially, the agreement was that at least 5000 t be caught south of 46° S. Subsequently, the catch limits, and the designated sub-areas to which they apply, have changed from year to year.

The TACC was reduced to 3600 t in 2011–12 (Table 1). The agreed catch limit for the East and South Chatham Rise is currently 3100 t (Table 3). A three-year staged process to reduce F to F_{MSY} was initiated on 1 October 2008. Under this approach, the catch limit was to be set at 4.5% ($F_{MSY} = M$) of the estimated current biomass in each year from 1 October 2010. However, for 2013–14 the TACC was increased to 4500 t (Table 1) in response to the increased biomass estimates following the discovery of the Rekohu plume.

The catch limit for the Sub-Antarctic has been substantially undercaught since 2009–10. However, the combined East and South Rise sub-area catch limits were exceeded by 450 t in 2005–06 and by 350 t in 2006–07 (100 t were taken against the allowance for research surveys). Taking the research allowance into account, catch limits for the combined east and south Rise sub-area have not been exceeded in subsequent years. Since 2004–05, 250 t of the ORH 3B TACC has been set aside for industry research surveys (Table 3), although this has sometimes been used in areas outside the East and South Chatham Rise.

Figure 2: ORH 3B sub-areas and the approximate position of other named fisheries outside of the Chatham Rise. The Spawning Box is in the western part of the East Rise (to the west of the vertical broken line at 175°W). The East and South Rise are currently managed as a single unit. The Arrow Plateau has been designated a Benthic Protected Area. The Sub-Antarctic is all areas below 46°S on the east coast, and 44°16'S on the west coast, except Puysegur.

Table 3: Catch limits (t) by designated sub-area within ORH 3B, as agreed between the industry and the Ministers responsible for fisheries since 1992–93. Note that East Rise includes the Spawning Box, closed between 1992–93 and 1994–95. Sub-area boundaries have varied somewhat between years. * South Rise included in East Rise catch limit. ** Arrow Plateau included in Sub-Antarctic.

Year	Northwest Chatham Rise	East Chatham Rise	South Chatham Rise	Puysegur	Arrow Plateau	Sub-Antarctic

† an additional 250 t set aside for industry research surveys.

‡ 8650 t allocated to the East and South Chatham Rise combined, with no more than 2000 t from the South Rise, and no more than 7250 t from the East Rise.

Combined East and South Rise catch not to exceed 7650 t; East Rise not to exceed 6500 t; South Rise catch not to exceed 1750 t.

§ In 2008–09, the catch from the spawning plume was not to exceed 3285 t.

β From 2010–11 to 2012–13, quota owners have agreed to avoid fishing the Northwest Rise.

Outside the Spawning Box, catches increased in the 1990s and catch rates have been highly variable, sustained largely by the discovery of new fishing areas. Flat areas on the Northwest Rise and several major hills on the South Rise were important in the late 1980s, but currently do not support their previous levels of catch, now accounting for less than 5% of the estimated catch. High catch rates can still occur, but these are less frequent than observed in the early years of the fishery. Catches from the Northwest Rise fell to near zero in 2010–11 as a result of an agreement among quota owners to avoid fishing in this area (Table 2). This agreement was extended to the 2011–12 and 2012–13 fishing years.

Between 1991–92 and 2000–01, more than half of the Chatham Rise catch came from four hill complexes: the Andes, Smith City and neighbours, Graveyard, and Big Chief and neighbours. All of these have shown a decline in unstandardised catch rate since the early years of the fishery, and in recent years, catch rates in these hill complexes have remained relatively low. After 2000–01, the proportion of the catch from these hill complexes decreased, as a greater proportion of the catch came from the Spawning Box (about 39% in 2008–09). In addition, large catches have been made in recent years outside of the spawning season, in recently developed areas of the southeast Rise. Catches from the Spawning Box taken during the spawning season (which peaks in July) have been relatively high since 2001–02, although unstandardised catch rates have been variable.

The first fishery to be developed south of the Chatham Rise was on Puysegur Bank, where spawning aggregations of orange roughy were found during a joint Industry-Ministry exploratory fishing survey in 1990–91. The fishery developed rapidly, but from 1993–94 catch limits were substantially under-caught. Catch limits were subsequently reduced from the initial level of 5000 t, and the industry implemented a catch limit of 0 t beginning in the 1997–98 fishing year (reported catches in 2004–05 and 2005–06 were taken during industry surveys). No fishing in this area occurred in 2010–11 in spite of an increase in the catch limit to 150 t (Table 3).

ORANGE ROUGHY (ORH 3B)

Exploratory fishing on the Macquarie Ridge south of Puysegur in 1993 led to the development of a fishery off the Auckland Islands. Total catch rose to around 900 t in 1994–95, but then dropped to less than 200 t by 1999–00, and catches have since been infrequent.

In 1993–94, catches were taken on the ‘Arrow Plateau’, and became the first major fishery to develop on the easternmost section of the Chatham Rise. A catch limit of 3000 t was put in place for 1994–95, with an additional limit of 500 t for each hill. Only a few hills in this area have been fished successfully, and the catch has never reached the catch limit, which was reduced to 1000 t by the early 2000s (Table 3). The Arrow Plateau was closed to orange roughy fishing when it was designated a Benthic Protected Area in 2007.

In 1995–96, large catches were reported on the southeast Pukaki Rise, with a catch total of over 3000 t. However, the catches dropped rapidly and the fishery effectively ceased within a few years. From 2001–02, a fishery developed on the northeast Pukaki Rise, including the area known as Priceless, where catches were mostly taken at the start of the fishing year. Catches at Priceless reached the feature limit of 500 t for each of the six years up to 2006–07, but catches and catch rates declined substantially from 2007–08, and have remained low since. Areas of the northeast Pukaki Rise outside of Priceless were developed in 2004–05 and also showed a rapid decline in catches and catch rates. By 2007–08, the fishery in the sub-Antarctic was limited to the Auckland Islands and northeast Pukaki Rise areas. Since 2008–09, the fishery has extended over a relatively wide area, but catches and catch rates have been low.

Catches of orange roughy have also been taken off the Bounty Islands (around 100–200 t per year from 1997–98 to 2004–05, but infrequently since then), off the Snares Islands (up to around 500 t per year, but infrequently in recent years), areas of the Macquarie Ridge (100–500 t per year from 2000–01 to 2004–05, and in 2008–09), and off Fiordland (around 500 t in 2000–01, but subsequent catches rapidly decreased).

1.2 Recreational fisheries

No recreational fishing for orange roughy is known in this quota management area.

1.3 Customary non-commercial fisheries

No customary non-commercial fishing for orange roughy is known in this quota management area.

1.4 Illegal catch

No information is available on illegal catch in this quota management area.

1.5 Other sources of mortality

There has been a history of catch overruns on the Chatham Rise because of lost fish and discards, and discrepancies in tray weights and conversion factors. In assessments, total removals from each part of the Chatham Rise were assumed to exceed reported catches by the overrun percentages in Table 4.

Table 4: Catch overruns (%) by year.

Year	1978–79	1979–80	1980–81	1981–82	1982–83	1983–84	1984–85	1985–86	1986–87	1987–88
Overrun	30	30	30	30	30	30	30	28	26	24
Year	1988–89	1989–90	1990–91	1991–92	1992–93	1993–94	1994–95 and subsequently			
Overrun	22	20	15	10	10	10	5			

For Puysegur and other southern fisheries there is no reason to believe that, if there was an overrun in catches, this shows any trend over time. For this reason, it was assumed that there was no overrun for this area.

Within the TAC an allowance of 5% of the TACC is allocated for other sources of mortality (currently 225 t).

2. BIOLOGY

Biological parameters used in this assessment are presented in the Biology section at the beginning of the Orange Roughy section.

3. STOCKS AND AREAS

For the purposes of this report the term “stock” refers to a biological unit with a single major spawning ground, in contrast to a “Fishstock” which refers to a management unit.

Genetically two main stocks are recognised within ORH 3B (Chatham Rise and Puysegur; Smith & Benson 1997) and these are considered to be distinct from stocks in adjacent areas (Cook Canyon and Ritchie Bank). However, it is likely, because of their geographical separation and discontinuities in the distribution of orange roughy, that concentrations of spawning fish on the Arrow Plateau, near the Auckland Islands, and west of the Antipodes Islands also form separate stocks.

Genetic data have been applied to define stock boundaries, both within ORH 3B, and between it and adjacent areas. Mitochondrial DNA shows that there are considerable differences between Puysegur fish and fish from the geographically adjacent areas Cook Canyon and Chatham Rise. Allozyme frequency studies suggest that Chatham Rise fish are distinct from those on the Ritchie Bank (ORH 2A). These data also suggest multiple stocks within the Chatham Rise, but do not indicate clear stock boundaries. Although there is significant heterogeneity amongst allozyme frequencies from different areas of the Rise, these frequencies varied as much in time (samples from the same location at different times) as in space (samples from different locations at the same time).

Chatham Rise

The stock structure of orange roughy on the Chatham Rise was comprehensively reviewed in 2008 (Dunn & Devine 2010). This review evaluated all available data as no single dataset seemed to provide definitive information about likely stock boundaries. The data analysed included: catch distribution and CPUE patterns; location of spawning and nursery grounds; inferred migrations; size, maturity and condition data; genetic studies, and habitat and natural boundaries.

There is evidence that a separate stock exists on the Northwest Rise. The Northwest Rise contains a large spawning ground on the Graveyard Hills, and also nursery grounds around, and primarily to the west of, the Graveyard Hills. There is a gap in the distribution of early juveniles (under 15 cm SL) between the Graveyard area and the Spawning Box at approximately 178°W. A research trawl survey found post-spawning adult fish to the west, but not to the east, of the Graveyard Hills, and a westerly post-spawning migration was inferred. Analyses of median length from commercial and research trawls found that orange roughy on the Northwest Chatham Rise and Graveyard Hills were smaller than those on the East Rise. A substantial decline in the size of 50% maturity after 1992 was found for both the Graveyard Hills and the Northwest Rise, but not for other areas. The only information that does not support the Northwest Rise being a separate stock is an indication from patterns in commercial catch rates that some fish arriving to spawn in the Spawning Box may come from the west (Coburn & Doonan 1994, 1997). Catch data and genetic studies do not shed any further light on stock structure. Oceanographic models suggest that a gyre to the east of the Graveyard may provide a mechanism for a separation between the Northwest Chatham Rise and the East Rise. Based on the available data, the Northwest Chatham Rise is considered to be a separate stock.

The separation of the Northeast Hills and Andes as separate stocks from the Spawning Box and Eastern Flats was based on observations of simultaneous spawning aggregations occurring on these hills, and because stock assessment models indicated a mismatch between the standardised CPUE trends. On the other hand, the occurrence of a continuous nursery ground throughout the area; similar trends in size of 50% maturity in each area; the essentially continuous habitat with similar environmental conditions and inferred post-spawning migrations from the Spawning Box towards the east Rise all suggest that all of these areas are a single stock. Analyses of median lengths from commercial catches showed no obvious differences between areas. In addition, the spawning

ORANGE ROUGHY (ORH 3B)

aggregations found on the Northeast Hills and Andes appear to have been minor compared to that in the Spawning Box. The spawning aggregation on the Northeast Hills is also associated with an increase in mean length and catch rates, suggesting that fish spawning on these hills are not resident, and thus are not separate from the surrounding area. Based on the available data the Northeast Hills and Andes are therefore considered to be from the same stock as the Spawning Box and Eastern Flats.

The only evidence to separate the eastern area of the South Rise (Big Chief and surrounds) from the East Rise is the lack of spawning migrations inferred from an absence of a seasonal effect in standardised CPUE analyses. The evidence that the Big Chief area is the same stock as the East Rise includes the fact that the nursery grounds and habitat are continuous; there were no splits between the areas identified from analyses of median length; and the fisheries are similar. The reports of spawning fish around Big Chief have been infrequent, and so are considered equivocal on stock structure. The Big Chief area is therefore considered part of the East Rise stock.

There is weak evidence that the area of the South Rise west of and including Hegerville is a separate stock. The evidence includes median length analyses which indicated a split in this area, and an oceanographic front at 177°W. However, very few catches of spawning orange roughy have been reported in this area, and there appears to be no substantial nursery ground. Both of these factors support the idea that this area does not have a separate stock. In the area to the west of the suggested split the fish are relatively small during spawning, and relatively large during non-spawning. Combined with a standardised CPUE which shows a decline in abundance around July (peak spawning), and a somatic condition factor which declines during September–November (post-spawning), this supports a hypothesis of adult fish leaving the area to spawn elsewhere.

The South Rise could provide feeding habitat for the stock, which is estimated to have had an initial biomass of over 300 000 t, an amount that was probably too large to inhabit only the East Rise. There is more evidence to support orange roughy in this area being part of the East Rise stock than there is to the contrary. The current hypothesis is that the area to the west of the current convergence may be relatively marginal habitat, where larger juvenile, maturing and adult orange roughy were once predominant, and there is little spawning and few juveniles because the water is relatively cold.

Based on these analyses, the Chatham Rise has been divided into two areas: the Northwest, and the East and South Rise combined (Figure 2). The centre of the Northwest stock is the Graveyard Hills. The centre of the East and South Rise stock is the Spawning Box during spawning, and the southeast corner of the Rise during non-spawning.

4. STOCK ASSESSMENT

No model-based stock assessments were conducted for ORH 3B stocks from 2007 to 2013 inclusive. This was primarily because the 2006 stock assessment, which assumed deterministic recruitment, showed an increasing trend in biomass which was not supported by recent biomass indices. Deterministic recruitment was assumed because ageing data were considered to be unreliable. With the successful assessment of the MEC stock in 2013, which used age data from the new ageing methodology (Tracey et al. 2007), there has been a return to model-based assessment in 2014. In addition to an update of the MEC stock assessment, three further stocks have also been assessed, including two stocks in ORH 3B (the Northwest Chatham Rise, the East and South Chatham Rise). There are no other reliable assessments for stocks within ORH 3B. Recruitment in all of these assessments has been derived from limited age data.

4.1 Northwest Chatham Rise

A Bayesian stock assessment was conducted for the Northwest Chatham Rise (NWCR) stock in 2014. This used age-structured population model fitted to acoustic-survey estimates of spawning biomass, a trawl-survey estimate of proportion-at-age and proportion-spawning-at-age, and a limited number of length frequencies from the commercial fishery.

4.1.1 Model structure

The model was single-sex and age-structured (1-100 years with a plus group), with maturity estimated separately (i.e., fish were classified by age and as mature or immature). A single-time step was used and the single fishery was assumed to be year-round on mature fish. Spawning was taken to occur after 75% of the mortality and 100% of mature fish were assumed to spawn each year.

The catch history was constructed from the Northwest catches in Table 2 using the catch over-run percentages in Table 4. Natural mortality was assumed to be fixed at 0.045 and the stock-recruitment relationship was assumed to follow a Beverton-Holt function with steepness of 0.75. The remaining fixed biological parameters are given in Table 2 of the Orange Roughy Introduction section.

4.1.2 Input data and statistical assumptions

There were three main data sources for observations fitted in the assessment: acoustic-survey spawning biomass estimates from the main spawning hills (Graveyard and Morgue); an age frequency and an estimate of proportion-spawning-at-age taken from a 1994 wide-area trawl survey; and length frequencies collected from the commercial fishery from 1989–2005.

Acoustic estimates

Three types of acoustic-survey estimates were available for use in the assessment: AOS estimates (from a multi-frequency towed system, e.g., see Kloser et al. 2011); 38 kHz estimates from a towed-body system; and 38 kHz estimates from a hull-mounted system. The reliability of the data from the different systems in each year was considered and estimates from the AOS and towed-body systems were used in the base model (Table 5). An alternative treatment of the available acoustic data was to include additional survey estimates from 2002 and 2004 (Table 5). All of the data in Table 5 were used in the sensitivity run labelled “Extra acoustics”.

Table 5: Acoustic survey estimates of spawning biomass used in the base model (excludes 2002 and 2004) and the sensitivity run “Extra acoustics” (uses all data). “GY” = Graveyard, “M” = Morgue, “O” = other hills. The CVs are those used in the model and do not include any process error.

Year	System	Frequency	Areas	Snapshots	Estimate (t)	CV (%)
1999	Towed-body	38 kHz	GY+M+O	1	8126	22
2002	Towed-body	38 kHz	GY+O	2	9414	20
2004	Hill-mounted	38 kHz	GY	6	2717	16
2012	AOS	38 kHz	GY	3	5550	17
	AOS	38 kHz	M	4	9087	11
2013	AOS	120 kHz	GY	1	7379	31

The acoustic estimates in 1999 and 2012 (total = 14 637 t, CV 17%) were assumed to represent “most” of the spawning biomass in each year. This was modelled by treating the acoustic estimates as relative biomass and estimating the proportionality constant (q) with an informed prior. The prior was normally distributed with a mean of 0.8 (i.e., “most” = 80%) and a CV of 19% (see orange roughy Introduction). The 2013 Graveyard estimate was modelled as relative biomass with an informed prior on the q with a mean of 0.3 (derived from the relative proportions of the Graveyard and Morgue estimates in 2012 with the 80% assumption).

Trawl survey data

A wide-area trawl survey of the northwest flats was conducted in late May and early June of 1994 (72 stations; Tracey and Fenaughty 1997). An age-frequency for the trawl-selected biomass was estimated using 300 otoliths selected using the method of Doonan et al (2013). The female proportion spawning-at-age was also estimated. These data were fitted in the model: age frequency (multinomial with an effective sample size of 60); proportion-spawning-at-age (binomial with effective sample size at each age equal to the number of female otoliths at age).

Length frequencies

The length frequencies from the previous assessment in 2006 were used: nine years of length-frequency data from the period 1989-97 were combined into a single length-frequency that was centred on the 1993 fishing year. Eight years of length-frequency data from the period 1998-2005 were combined into a single length-frequency that was centred on the 2002 fishing year. The effective sample size was set at 1/6 of the number of tows for each period: 19 for the “1993” period and 35 for the “2002” period (A. Hicks pers. comm.). The data were assumed to be multinomial.

4.1.3 Model runs and results

In the base model, the acoustic estimates from 1999, 2012, and 2013 were used and natural mortality (M) was fixed at 0.045. There were five main sensitivity runs: estimate M ; add the extra acoustic data and fix M ; add the extra acoustic data and estimate M ; and the LowM-High q and HighM-Low q “standard” runs (see orange roughy Introduction).

In the base model, the main parameters estimated were: virgin (unfished, equilibrium) biomass (B_0), maturity ogive, trawl-survey selectivity, CV of length-at-mean-length-at-age for ages 1 and 100 years (linear relationship assumed for intermediate ages), and year class strengths (YCS) from 1940 to 1979 (with the Haist parameterisation and “nearly uniform” priors on the free parameters).

Model diagnostics

The model provided good MPD fits to the data (Figures 3 & 4). The acoustic indices, free to “move” somewhat as they are relative, were very well fitted with the normalised residuals close to zero except in 2013 (Figure 3, top right). The estimated acoustic qs were not very different from the mean of the informed priors (Figure 3, bottom). The same is not quite true for the MCMCs, because, although the posteriors for the acoustic qs are not very different from the priors, there has clearly been some movement (Figure 5).

Numerous MPD sensitivity runs were performed. These showed that the main drivers of the estimated stock status were natural mortality (M) and the means of the acoustic q priors (lower M and higher mean q give lower stock status; higher M and lower mean q give higher stock status).

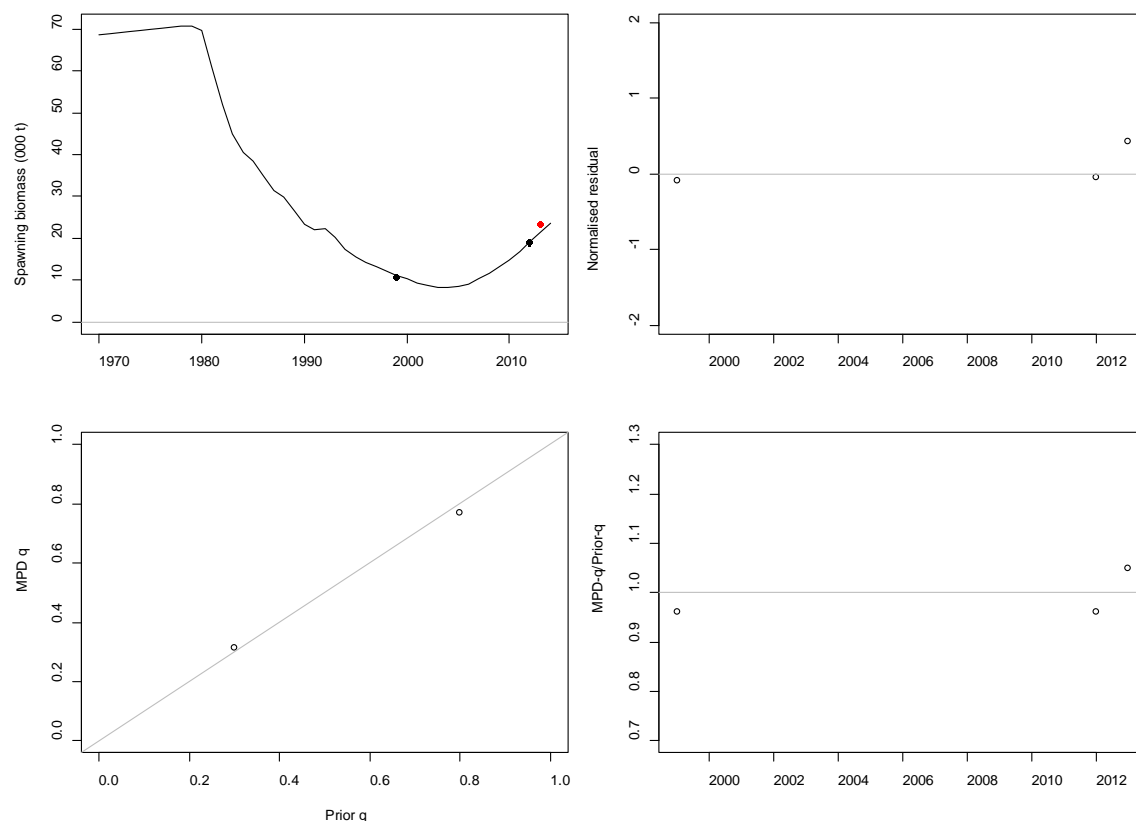

Figure 3: NWCR, base, MPD: fits to the acoustic indices: (top) spawning biomass trajectory and unscaled acoustic indices; normalised residuals; (bottom) estimated qs as a function of the mean of the q prior; the ratio of the estimated q to the mean of the q prior.

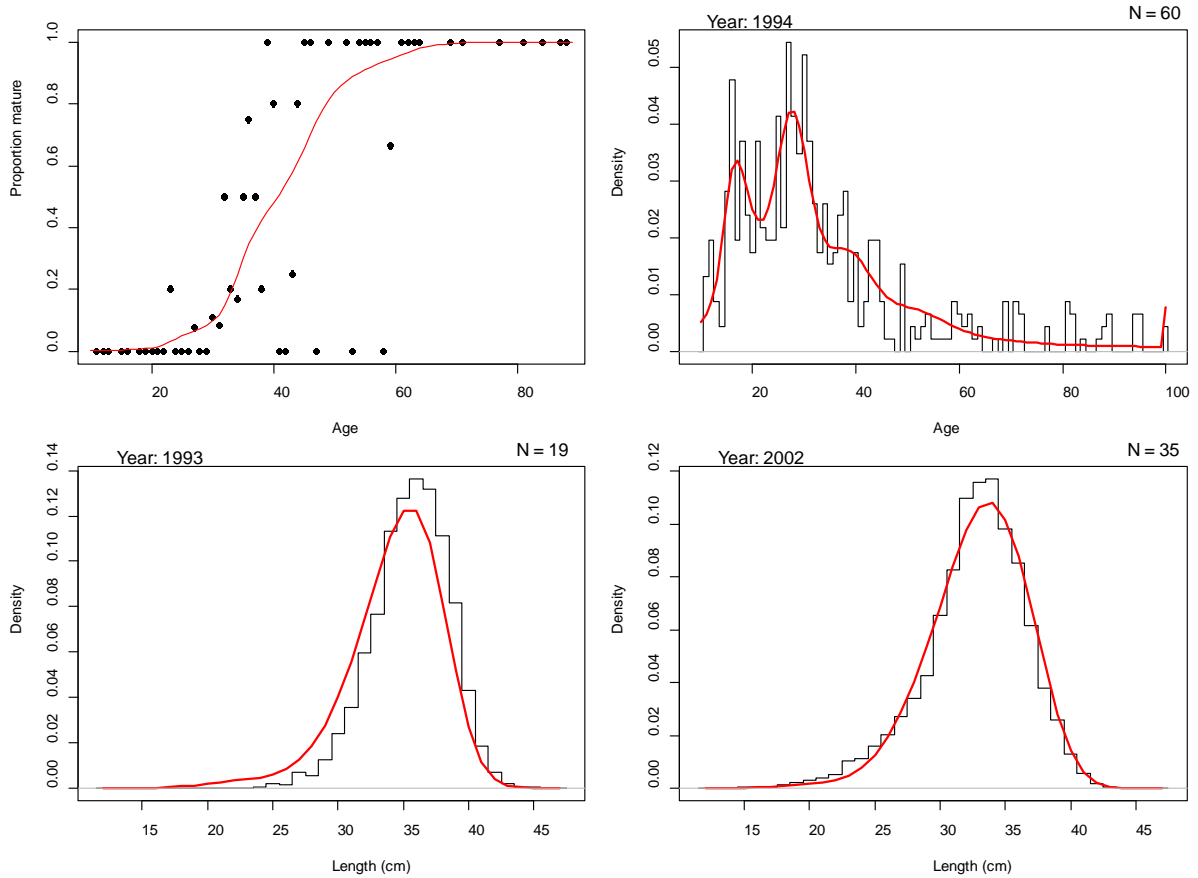

Figure 4: NWCR, base, MPD fits: (observations in black; predictions in red): (top) proportion mature at age; trawl survey age frequency ; (bottom) commercial length frequencies (N is the effective sample size).

Figure 5: NWCR base, MCMC diagnostics: prior and posterior distributions for the two acoustic q s (left, mean q -prior = 0.8; right, mean q -prior = 0.3). The red dot shows the median of the posterior.

MCMC results

For the base model, and the sensitivity runs, MCMC convergence diagnostics were excellent. Virgin biomass, B_0 , was estimated to be between 64 000–68 000 t for all runs (Table 6). Current stock status was similar across the base and the first three sensitivity runs (Table 6). The slightly lower stock status when M was estimated reflects the lower estimates of M (0.040 rather than 0.045). For the two “bounding” runs, where M and the mean of the acoustic q priors were shifted by 20%, median current stock status was estimated outside of the biomass target range of 30–40% B_0 for both runs (Table 6).

Table 6: NWCR, MCMC estimates of virgin biomass (B_0) and stock status (B_{2014} as % B_0) for the base model and five sensitivity runs.

	M	B_0 (000 t)	95% CI	B_{2014} (% B_0)	95% CI
Base	0.045	66	61-76	37	30-46
Extra acoustics	0.045	64	60-69	34	29-41
Estimate M	0.041	68	61-78	34	26-45
Extra & Est. M	0.040	67	60-74	32	25-40
LowM-Highq	0.036	68	64-76	28	23-36
HighM-Lowq	0.054	66	59-78	46	38-56

For the base model, the stock is now considered to be fully rebuilt according to the Harvest Strategy Standard (at least a 70% probability that the lower end of the management target range of 30–40% B_0 has been achieved).

The estimated YCS showed little variation across cohorts (Figure 6). The variation in the more recent (true) YCS is due to variation in depletion levels across the MCMC samples (and hence different levels of recruitment were generated from the stock-recruitment function).

Figure 6: NWCR base, MCMC estimated “true” YCS (R_t/R_0). The box in each year covers 50% of the distribution and the whiskers extend to 95% of the distribution.

The estimated spawning-stock biomass (SSB) trajectory showed a declining trend from 1980 (when the fishery started) through to 2004 when the biomass was About as Likely as Not (40-60%) to be below the soft limit (Figure 7). Since 2005 the estimated biomass has increased steadily.

Figure 7: NWCR base, MCMC estimated spawning-stock biomass trajectory. The box in each year covers 50% of the distribution and the whiskers extend to 95% of the distribution. The hard limit (red), soft limit (blue), and biomass target range (green) are marked by horizontal lines.

Fishing intensity was estimated in each year for each MCMC sample to produce a posterior distribution for fishing intensity by year. Fishing intensity is represented in term of the median exploitation rate and the Equilibrium Stock Depletion (ESD). For the latter, a fishing intensity of $U_{x\%B_0}$ means that fishing (forever) at that intensity will cause the SSB to reach deterministic equilibrium at $x\% B_0$ (e.g., fishing at $U_{30\%B_0}$ forces the SSB to a deterministic equilibrium of 30% B_0). Fishing intensity in these units is plotted as 100–ESD so that fishing intensity ranges from 0 ($U_{100\%B_0}$) up to 100 ($U_{0\%B_0}$).

Estimated fishing intensity was above $U_{20\%B_0}$ for most of the history of the fishery; it was briefly in the target range ($U_{30\%B_0}$ – $U_{40\%B_0}$) from 2006–2010 before dropping substantially when the industry agreed to curtail fishing the NWCR in 2011 (Figure 8).

Figure 8: NWCR base, MCMC estimated fishing-intensity trajectory. The box in each year covers 50% of the distribution and the whiskers extend to 95% of the distribution. The fishing-intensity range associated with the biomass target of 30–40% B_0 is marked by horizontal lines.

Biological reference points, management targets and yield

MCMC estimates of deterministic B_{MSY} and associated values were produced for the base model. The yield at 35% B_0 (the mid-point of the target range) was also estimated. There is very little variation in the reference points and associated values across the MCMC samples (Table 7).

There are several reasons why deterministic B_{MSY} is not a suitable target for use in fisheries management. First, it assumes a harvest strategy that is unrealistic in that it involves perfect knowledge (current biomass must be known exactly in order to calculate the target catch) and annual changes in TACC (which are unlikely to happen in New Zealand and not desirable for most stakeholders). Second, it assumes perfect knowledge of the stock-recruit relationship, which is often poorly known. Third, it would be very difficult with such a low biomass target to avoid the biomass occasionally falling below 20% B_0 , the default soft limit according to the Harvest Strategy Standard.

Table 7 : NWCR base, MCMC estimates of deterministic equilibrium SSB and long-term yield (% B_0 and tonnes) for U_{MSY} and $U_{35\%B_0}$. The equilibrium SSB at U_{MSY} is deterministic B_{MSY} and the yield is deterministic MSY.

Fishing intensity		SSB (% B_0)	Yield (% B_0)	Yield (t)
U_{MSY}	Median	23.7	2.1	1391
	95% CI	23.2-24.7	2.0-2.2	1277-1593
$U_{35\%B_0}$	Median	35.0	2.0	1322
	95% CI		1.9-2.1	1214-1512

The estimate of yield associated with $U_{35\%B_0}$ for the 2014-15 fishing year is 1414 t (95% CI 1069-1984 t).

Projections

Five year projections were conducted (with resampling from the last 10 estimated YCS) for two different constant catch assumptions: 750 t (the current catch limit); and 1400 t (the current estimated yield at $U_{35\%B_0}$). In each case a 5% over-run was assumed. Projections were done for the base model and also for the LowM-Highq model (as a “worst case” scenario).

At the current catch limit (750 t), SSB is predicted to increase over the next five years even for the LowM-Highq model (Figure 9). At the catch associated with $U_{35\%B_0}$ (1400 t), SSB is predicted to rise slightly and then stay steady for both models (Figure 10). For both models and both constant catch scenarios, the estimated probability of SSB going below the soft or hard limits is virtually zero (the maximum is 0.01 for the soft limit in the latter years for LowM-Highq at 1400 t).

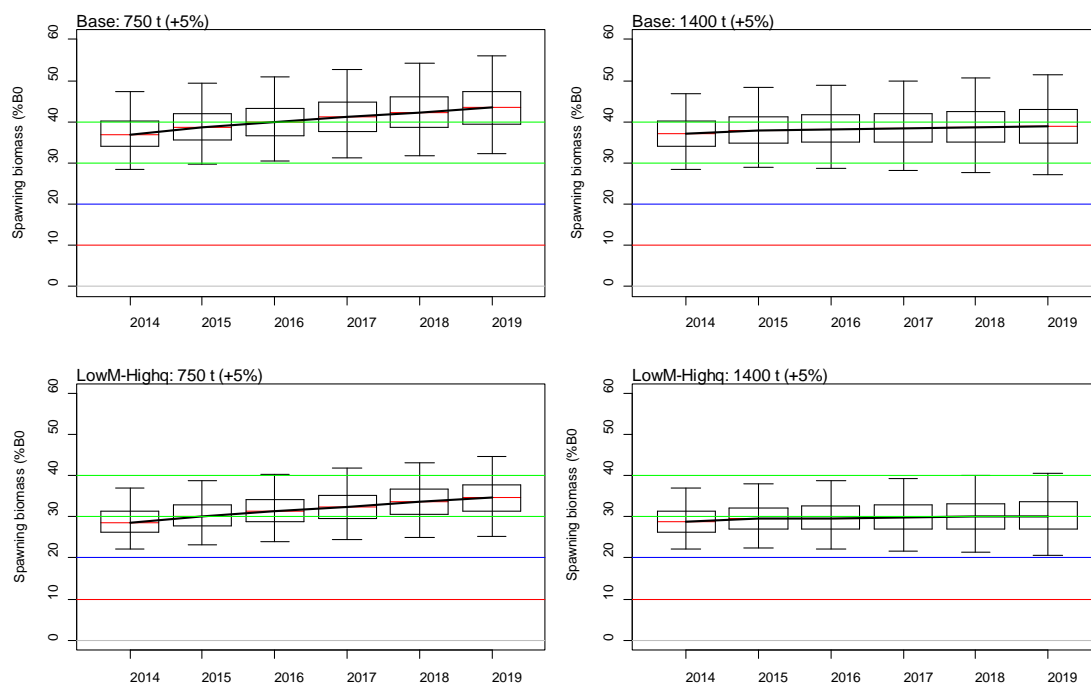

Figure 9: NWCR base, MCMC projections. The box in each year covers 50% of the distribution and the whiskers extend to 95% of the distribution. The projections are for the model and annual catch indicated (a 5% over-run was included in each year). The target range is indicated by horizontal green lines.

4.2 East and South Chatham Rise

A Bayesian stock assessment was conducted for the East and South Chatham Rise (ESCR) stock in 2014. This used an age-structured population model fitted to acoustic-survey estimates of spawning biomass, trawl-survey biomass indices, age frequencies from spawning aggregations, and length frequencies from trawl surveys and commercial fisheries.

4.2.1 Model structure

The model was single-sex and age-structured (1-100 years with a plus group), with maturity estimated separately (i.e., fish were classified by age and as mature or immature). A single-time step was used and four year-round fisheries, with logistic selectivities, were modelled: Box & flats, Eastern hills, Andes, and South Rise. These fisheries were chosen following Dunn (2007) who assessed the Box & flats, Eastern hills, and Andes as separate stocks and hence had already prepared length frequency data for those fisheries. No length frequencies were available from the South Rise fishery and its selectivity was assumed to be the same as the Andes (so effectively there were three fisheries in the model). Spawning was taken to occur after 75% of the mortality and 100% of mature fish were assumed to spawn each year.

The catch history was constructed using the catches given in Dunn (2007) from 1979-80 to 2002-2003 and from a new data extract from MPI for 2003-04 to 2012-13 (with total ORH 3B reported catch apportioned across areas using catch proportions from estimated catch on TCEPR forms). The over-run percentages in Table 4 were applied. Natural mortality was assumed fixed at 0.045 and the stock-recruitment relationship was assumed to follow a Beverton-Holt function with steepness of 0.75. The remaining fixed biological parameters are given in Table 2 of the Orange Roughy Introduction section.

In one sensitivity run, which assumed that the spawning plume first found near Rekohu canyon in 2010 had always existed, a spatially-explicit model structure was used. There were four areas to allow for the three known spawning sites (Rekohu, Old-plume¹, the Crack) and an additional area to hold the remaining spawning fish. The areas were only used at (an instantaneous) spawning time to allow the fitting of area-specific data (acoustic estimates and age frequencies). The four year-round fisheries were unchanged.

4.2.2 Input data and statistical assumptions

There were four main data sources for observations fitted in the assessment: acoustic-survey spawning biomass estimates from the Old-plume (2002–2013), Rekohu (2011–2013) and the Crack (2011, 2013); age frequencies from the spawning areas (2012 and 2013); trawl survey biomass indices and length frequencies; and early length frequencies collected from the commercial fisheries.

Acoustic estimates

The Old plume was acoustically surveyed as early as 1996, but the survey estimates are only considered to represent a consistent time series from 2002–2012 (see Cordue 2008; Hampton et al. 2008, 2009, 2010; Doonan et al. 2012). Like the Rekohu plume, that was first noted in 2010 and first surveyed in 2011, the Old plume occurs on an area of flat bottom and can be adequately surveyed using a hull-mounted transducer. In 2011 and 2013, an additional spawning area was surveyed; known as the Crack (also known as Mt. Muck), it is an area of rough terrain which requires a towed-body or trawl-mounted system to be used to reduce the height of the shadow or dead zone (i.e., with the transducer at a depth of about 500–700 m).

The estimates selected by the DWFAWG for use in the stock assessment are shown in Table 8. In 2013 there were a variety of estimates to choose from as surveys were conducted with a hull-mounted system and a multi-frequency AOS system mounted on a trawl net. In order to make the estimates as comparable as possible across years only the 38 kHz estimates were used and those from the hull-mounted system were weather-adjusted in the same way as earlier estimates (see presentations from Kloster and Ryan to the DWFAWG meetings in 2013 and 2014).

¹ For clarity, what was previously described as the Spawning plume¹ located in the Spawning Box has been renamed the 'Old-plume' so as to differentiate it from the Rekohu plume, which is also a spawning plume.

Table 8: Acoustic estimates of average pluming spawning biomass in the three main spawning areas as used in the assessment. All estimates were obtained from surveys on *FV San Wataki* from 38 kHz transducers. Each estimate is the average of a number of snapshots as reflected by the estimated CVs.

	Old plume		Rekohu		Crack	
	Estimate (t)	CV (%)	Estimate (t)	CV (%)	Estimate (t)	CV (%)
2002	63 950	6				
2003	44 316	6				
2004	44 968	8				
2005	43 923	4				
2006	47 450	10				
2007	34 427	5				
2008	31 668	8				
2009	28 199	5				
2010	21 205	7				
2011	16 422	8	28 113	18	6 794	21
2012	19 392	7	27 121	10		
2013	16 312	25	29 890	14	5 471	15

A key question that needed to be answered in order to use the acoustic data appropriately is: how long has the Rekohu plume been in existence? If the Rekohu plume has always existed (and was not discovered until 2010) then it would be one of three major spawning sites and could be modelled as such along with the Old plume and the Crack. This would imply that the Old-plume time series was tracking a consistent part of the spawning biomass (and its decline over time was therefore an important indicator of stock status). If, on the other hand, the Rekohu plume had very recently formed, this would imply that the Old-plume time series was a biomass index only up until the year before the Rekohu plume came into existence.

In the base model, it is assumed that the Old-plume time series cannot be relied on to provide a consistent index for any part of the spawning biomass. In 2011 and 2013, the estimates of average spawning biomass across the three areas were summed to form comparable indices for each year. The 2012 estimates from Rekohu and the Old-plume were summed to provide a 2012 index with a different proportionality constant or q than the preceding or following years. The Old-plume indices from 2002–2010 were used, but each point in the time series was given its own q . Informed priors were used for all of the qs in the Old-plume series, for the 2012 biomass index and the indices comprising 2011 and 2013 observations.

For 2011 and 2013, it was assumed that “most” of the biomass was being indexed so the “standard” acoustic q prior was used: lognormal (mean = 0.8, CV = 19%) (see orange roughy Introduction). The mean of the q prior for 2012 was derived from the observed biomass proportions across the three areas and the assumption that 80% of the spawning biomass was indexed in 2011 and 2013, which gave a mean of 0.7 for the 2012 index., a reflection that this index did not include an estimate for the Crack. For 2002 to 2010 the means of the q priors were assumed to decrease linearly from 0.7 (2002) down to 0.30 (2010), reflecting the gradual increase in the relative importance of the Rekohu plume. The linear sequence was derived by assuming 0.7 in 2002 (i.e., assuming that the Rekohu plume did not exist and only the Crack was missing from the survey estimate) and using the observed biomass proportions in 2011 with the 80% assumption (which gave the Old-plume being about 25% of the total spawning biomass). To reflect the increased uncertainty in the acoustic qs in years other than 2011 and 2013, the priors were given an increased CV of 30%.

For the sensitivity run where the Rekohu plume was assumed to have always existed, the specification of priors was done by splitting the two parts of the standard acoustic q prior. The proportion of spawning biomass indexed across all three areas combined was assigned a *Beta* (8,2) prior (which has a mean of 0.8). This is the availability part of the standard acoustic q prior. A single q was assumed for the spawning biomass estimates in each area and this was given the target strength part of the standard acoustic q prior (which has a mean of 1).

Trawl survey data

Research trawl surveys of the Spawning Box during July were completed from 1984 to 1994, using three different vessels: *FV Otago Buccaneer*, *FV Cordella*, and *RV Tangaroa* (Figure 10). A

consistent area was surveyed using fixed station positions (with some random second phase stations each year).

Figure 10: The Spawning Box trawl survey biomass indices (assuming a catchability of 1 for each vessel), with 95% confidence intervals shown as vertical lines. Vessels indicated as B, *FV Otago Buccaneer*; C, *FV Cordella*; T, *RV Tangaroa*.

The biomass indices were fitted as relative indices with a separate time series for each vessel (with uninformed priors on the q s). The second point in the Tangaroa time series, although very large (driven by a single high catch), has a large CV and so is unlikely to have had much effect on the assessment results.

Data from two wide-area surveys by *Tangaroa* in 2004 and 2007 were also used. These surveys covered the area which extends from the western edge of the Spawning Box around to the northern edge of the Andes. The area surveyed did not include the Old-plume, the Northeast Hills, or the Andes. The survey used a random design over sixteen strata grouped into five sub-areas. The trawl net used was the full-wing and relatively fine mesh ‘ratcatcher’ net. The surveys covered the same survey area as the Spawning Box trawl surveys from 1984 to 1994 as well as additional strata to the east. In 2007, the survey ran from 4–27 July and 62 trawl tows were completed. In 2004, the survey ran from 7–29 July and 57 trawl tows were completed.

The surveys had almost identical estimates of total biomass in each year (17 000 t) with low CVs (10% and 13% respectively). They were fitted as relative biomass with an uninformed prior on the q .

Length frequencies

The length frequencies from all of the trawl surveys were fitted in the model as multinomial random variables. Effective sample sizes (N) were taken from Dunn (2007) for the Spawning Box surveys and were assumed equal to the number of tows for the wide-area surveys (across all surveys the effective N s ranged from about 20–80).

Length frequencies from the commercial fisheries developed by Dunn (2007) were also fitted in the model. These were fitted as multinomial with effective sample sizes ranging from 8–38.

Age frequencies

Age frequencies were developed for the Old-plume and Rekohu plume in 2012 and 2013 and also for the Crack in 2013 (Ian Doonan, NIWA, pers. comm.). Approximately 300 otoliths were randomly selected from each area in 2012 and 250 from each area in 2013. In 2012, the fish in the Old-plume were noted to be generally older than those in the Rekohu plume. This pattern was also apparent in 2013 (Figure 11). The fish from the Crack, showed a mixture of ages from new spawners (20–30 years) through to much older fish (80–100 years) (Figure 11). In the base model, the age frequencies were combined across areas and fitted as multinomial with effective sample sizes of 50 and 60 respectively (reflecting the low number of trawls from which samples were taken).

ORANGE ROUGHY (ORH 3B)

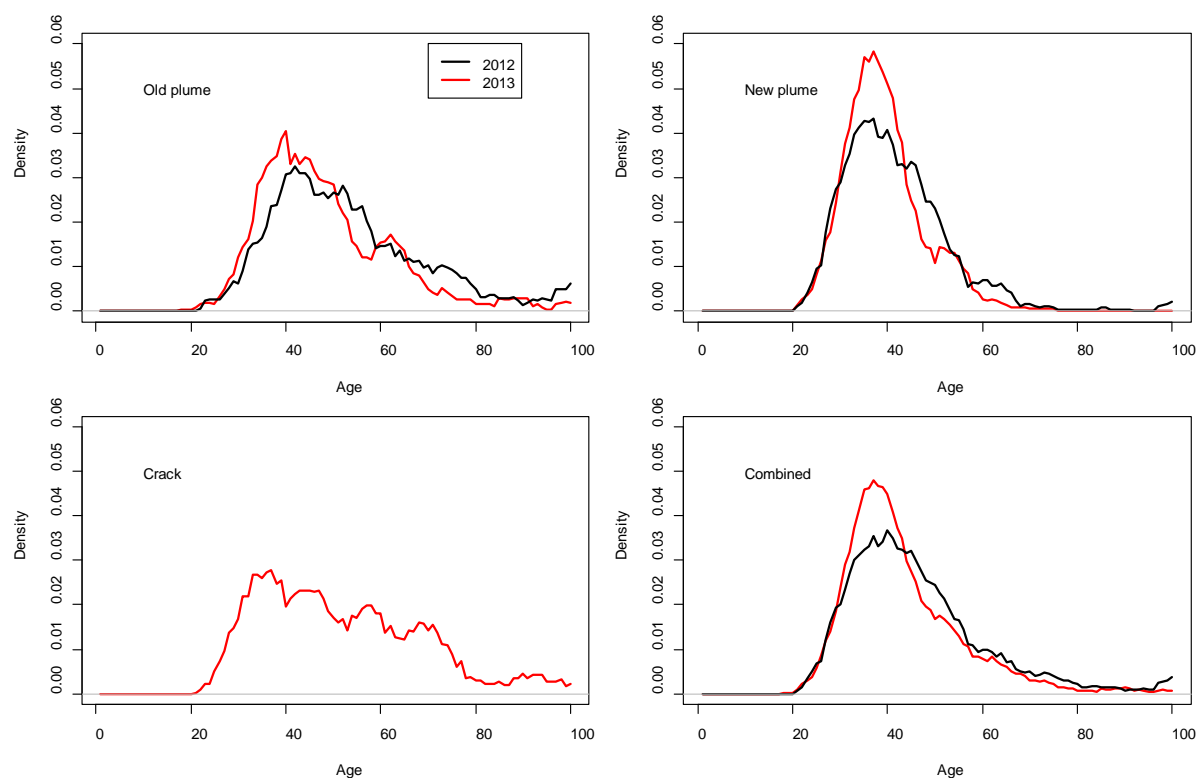

Figure 11: ESCR: smoothed spawning season age frequencies for the Old-plume (2012, 2013), Rekohu plume (2012, 2013), the Crack (2013) and for all three areas combined (2012, 2013).

4.2.3 Model runs and results

In the base model, the Old-plume time series was assumed to be unreliable in terms of trend and therefore each point from 2002 to 2010 was given its own q ; also, natural mortality (M) was fixed at 0.045. There were several important sensitivity runs: assume that the Rekohu plume had always existed; assume that it first occurred in 2007; assume it first occurred in 2010; estimate M ; adjust M and the mean of the priors by 20% (the standard LowM-Highq and HighM-Lowq runs, see orange roughy Introduction).

In the base model, the main parameters estimated were: virgin (unfished, equilibrium) biomass (B_0), maturity ogive, trawl-survey selectivities, fisheries selectivities, CV of length-at-mean-length-at-age for ages 1 and 100 years (linear relationship assumed for intermediate ages), and year class strengths (YCS) from 1930 to 1990 (with the Haist parameterisation and “nearly uniform” priors on the free parameters). There were also the numerous acoustic and trawl-survey q s.

Model diagnostics

The base model provided good MPD fits to the data. The MPD fits to the acoustic indices were excellent with normalised residuals all very small (Figure 12). Most of the MPD estimated q s were lower than the corresponding means of the priors, but the lowest ratio was only about 0.7 (Figure 12). The posteriors for the acoustic q s were shifted to the left of the priors for 2011 & 2013 and also for 2012, but remained well within the prior distribution (Figure 13). For the Old-plume time series, posteriors were sometimes shifted to the left of the priors but also sometimes to the right (e.g., see Figure 13 for 2002 and 2003) and the ratio of the mean of the posterior to the mean of the prior had a limited range from 0.85 (2003) to 1.2 (2006). The normalised residuals of the acoustic indices for the base MCMC model were also excellent, showing no apparent trend (Figure 14).

The MPD fits to the trawl indices were good but the model-predicted biomass had a shallower decline than that estimated from the indices from the *Buccaneer* and *Cordella* surveys (Figure 15). Also, the model does not fit the very large increase in the *Tangaroa* Spawning Box survey (Figure 15).

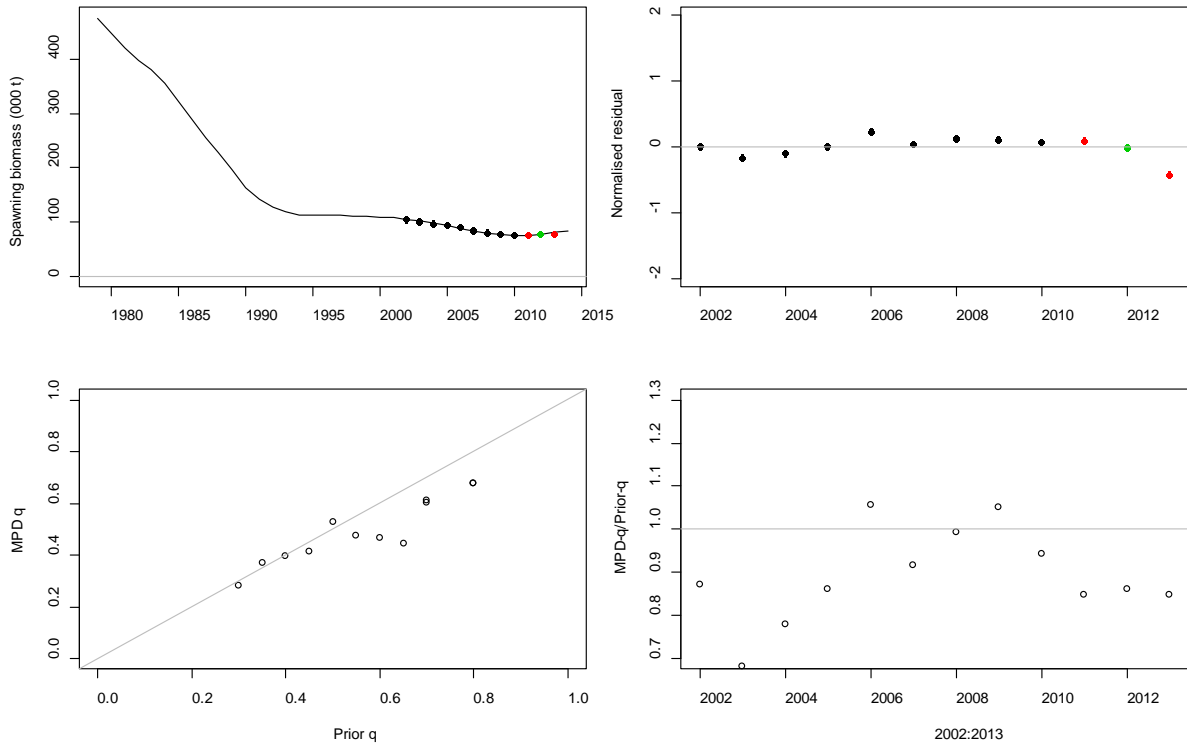

Figure 12: ESCR, MPD, base: fit to the acoustic indices: (top) spawning biomass trajectory and unscaled acoustic indices; normalised residuals; (bottom) estimated qs as a function of the mean of the q prior; the ratio of the estimated q to the mean of the q prior.

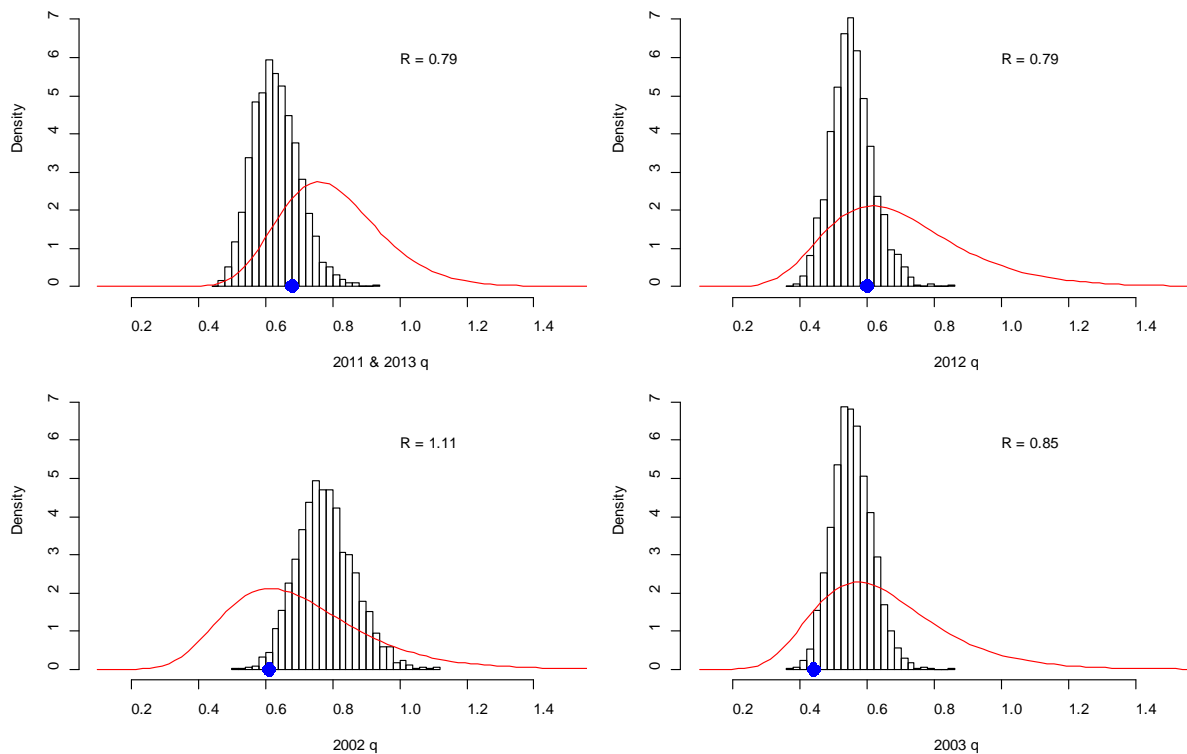

Figure 13: ESCR, MCMC base: prior (in red) and posterior distributions for a selection of acoustic qs . The blue dot is the MPD estimate and R is the ratio of the mean of the posterior to the mean of the prior.

ORANGE ROUGHY (ORH 3B)

Figure 14: ESCR, MCMC base: normalized residual for the acoustic indices. The box covers 50% of the distribution for each index and the whiskers extend to 95% of the distribution.

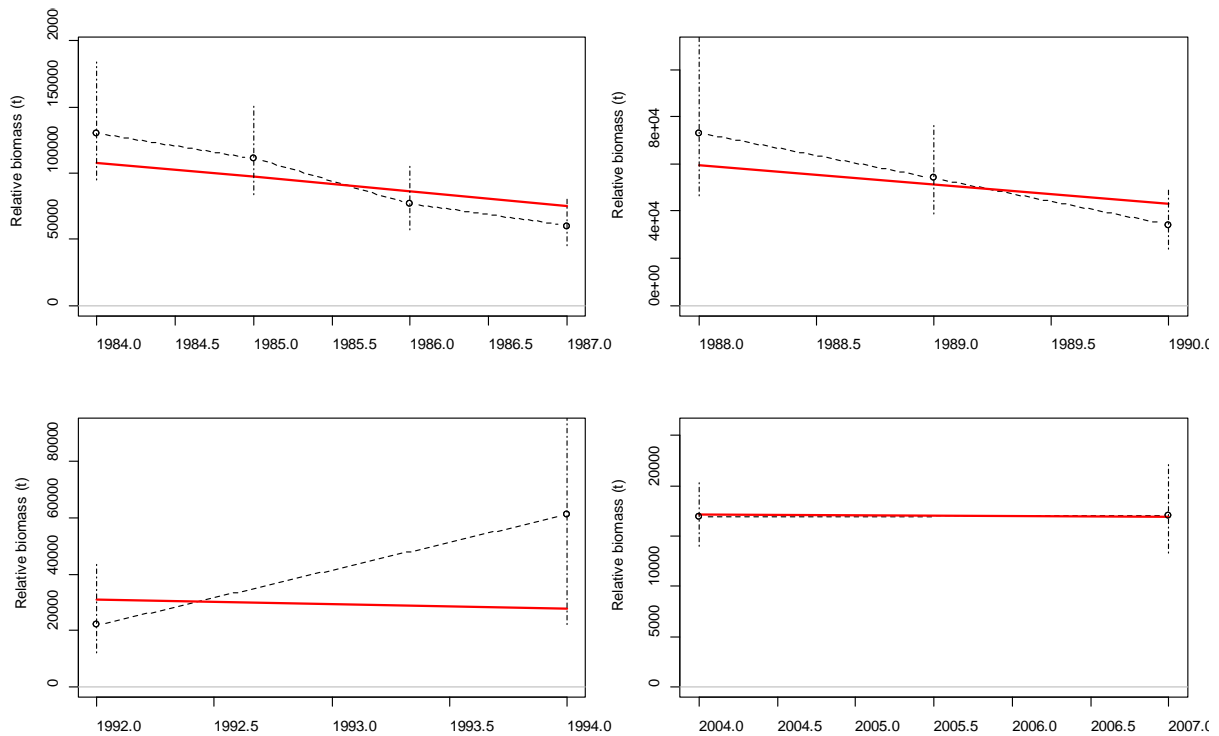

Figure 15: ESCR, MPD base: fits (in red) to the trawl-survey biomass indices (from top to bottom and left to right: *Buccaneer*, *Cordella*, *Tangaroa*, wide-area *Tangaroa*).

The fits to the age frequencies are as good as can be expected given the inconsistent shape of the age frequencies in the two consecutive years (Figure 16). The inconsistency is not caused by having the Crack included in 2013 and not 2012; the problem is too many 30-40 year old fish in 2013 (whereas the Crack had a wide mix of ages).

Figure 16: ESCR, MPD base: fits (in red) to the spawning season age frequencies. N is the effective sample size.

The MPD fits to the commercial length frequencies were excellent except the 1990 Box and flats length frequency (see Figure 17). Likewise the fits to the trawl survey length frequencies were excellent (e.g., see Figure 18). The long tail to the left, which was present in all of the trawl survey length frequencies from the Spawning Box, was easily fitted in the 2014 models, as selectivities were fitted for mature and immature fish. The three Spawning Box trawl surveys all had a common immature selectivity which allowed a small proportion of the immature fish to be selected (and hence to fit the left-hand tail). The *Tangaroa* wide-area trawl survey also had separate mature and immature selectivities which allowed a much larger proportion of immature fish to be selected and hence allowed a very good fit to the broad mode of the length frequencies (Figure 18).

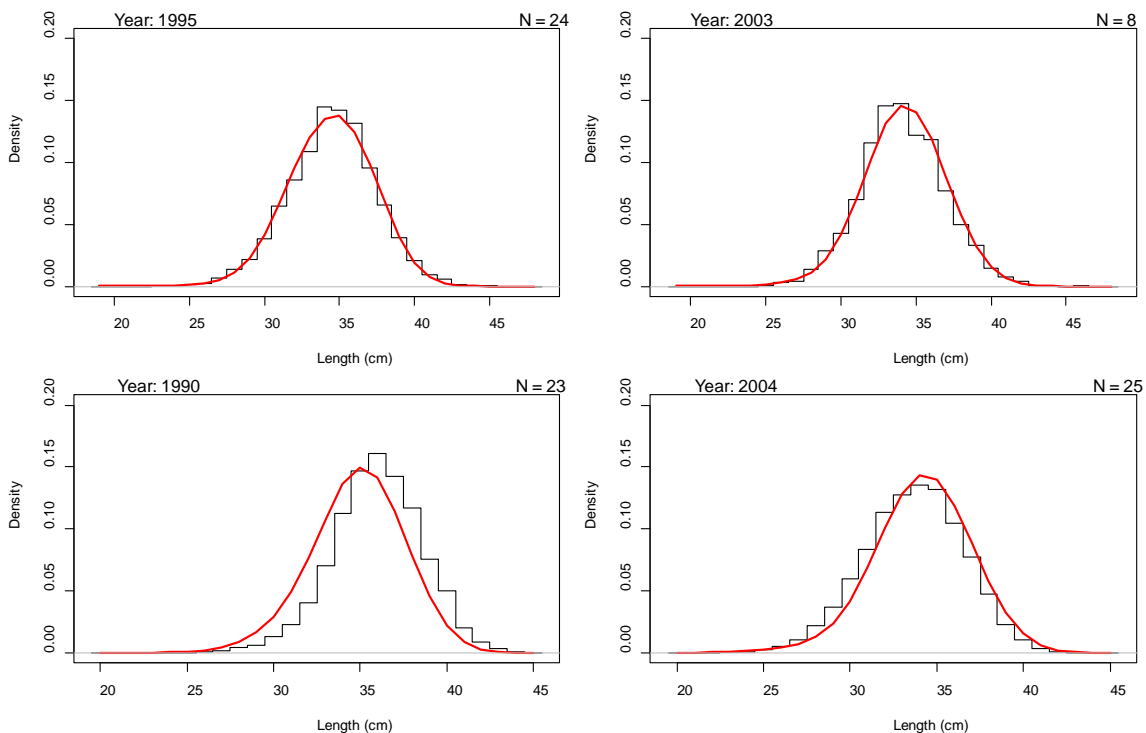

Figure 17: ESCR, MPD base: fits (in red) to the commercial length frequencies for the Eastern hills (top) and the Box and flats (bottom). N is the effective sample size.

ORANGE ROUGHY (ORH 3B)

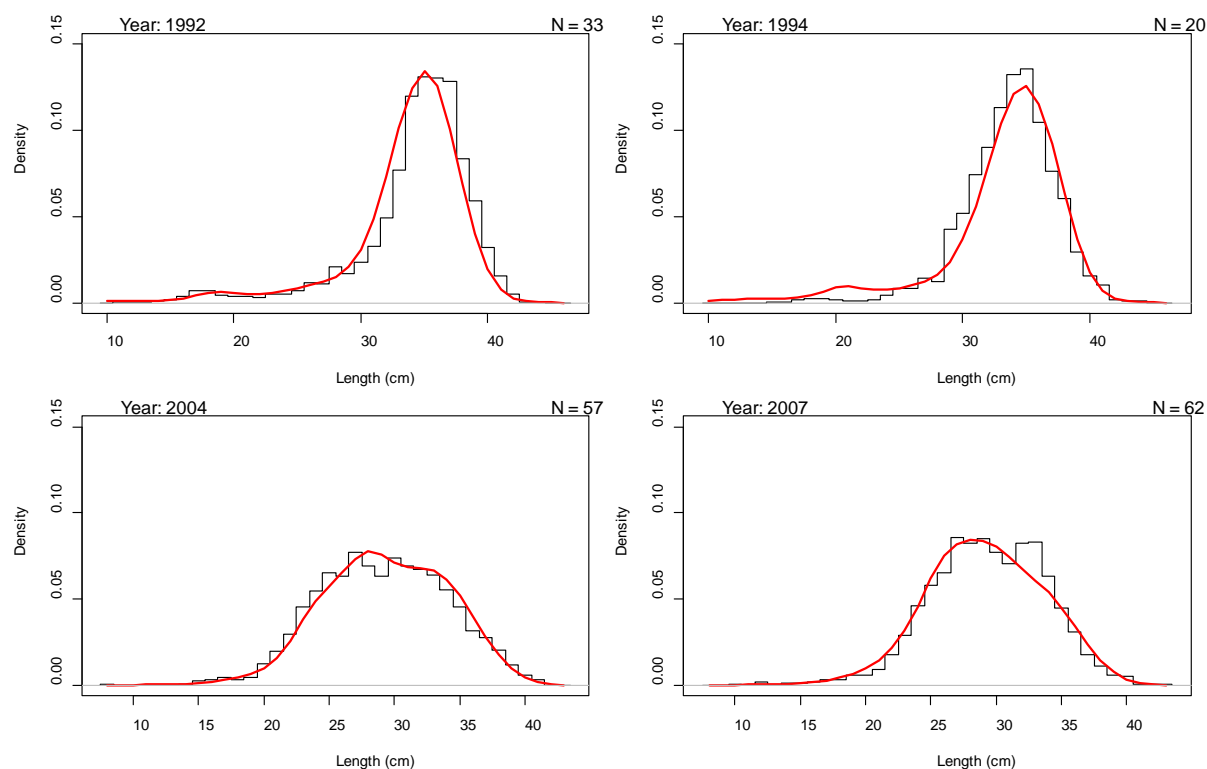

Figure 18: ESCR, MPD base: fits (in red) to the *Tangaroa* length frequencies for the Spawning Box (top) and the wide-area surveys (bottom). N is the effective sample size.

Numerous sensitivity runs were conducted at the MPD stage. Model estimates were robust to changes in effective sample sizes for composition data. The model was also robust to changes in M (0.03, 0.06 compared to base of 0.045) or changes in the mean of the acoustic q priors for 2011 & 2013 (0.6, 0.9 compared to base of 0.8). Major differences in the MPD estimate of current stock status occurred when the acoustic indices were halved or doubled, also and when deterministic recruitment was assumed (respectively: 14% B_0 , 39% B_0 , and 35% B_0 , compared to the base estimate of 24% B_0).

The sensitivities that explored the timing of the appearance of the Rekohu plume provided another validation for the robustness of the base model estimates. The “Always” model (which assumed that the Rekohu plume had always existed) provided an adequate fit to the data, but the results lacked credibility in three respects: (i) the posterior distribution for the acoustic q was pushed a long way to the right of the prior (Figure 19), (ii) as was the posterior for the proportion of spawning biomass being indexed by the three spawning areas combined (Figure 19), and (iii) the model estimated that the Rekohu plume had contained over 100,000 t of spawning biomass up until the early 1980s (Figure 20), which seemed unlikely, given the high level of fisheries exploration at that time (it also seemed unlikely that the fleet would have missed the 40-50,000 t estimated to have existed in the early 1990s when the spawning box (Old plume) was closed and the fleet may have been actively searching for other aggregations). These three factors combined caused the DWFAWG to conclude that the “Always” run was not a credible alternative to the base model.

Figure 19: ESCR, MCMC: “Always” sensitivity run: prior (in red) and posterior distributions for the acoustic q (left) and the proportion of spawning biomass available to the Old-plume, Rekohu plume, and the Crack combined (right). R is the ratio of the mean of the posterior to the mean of the prior.

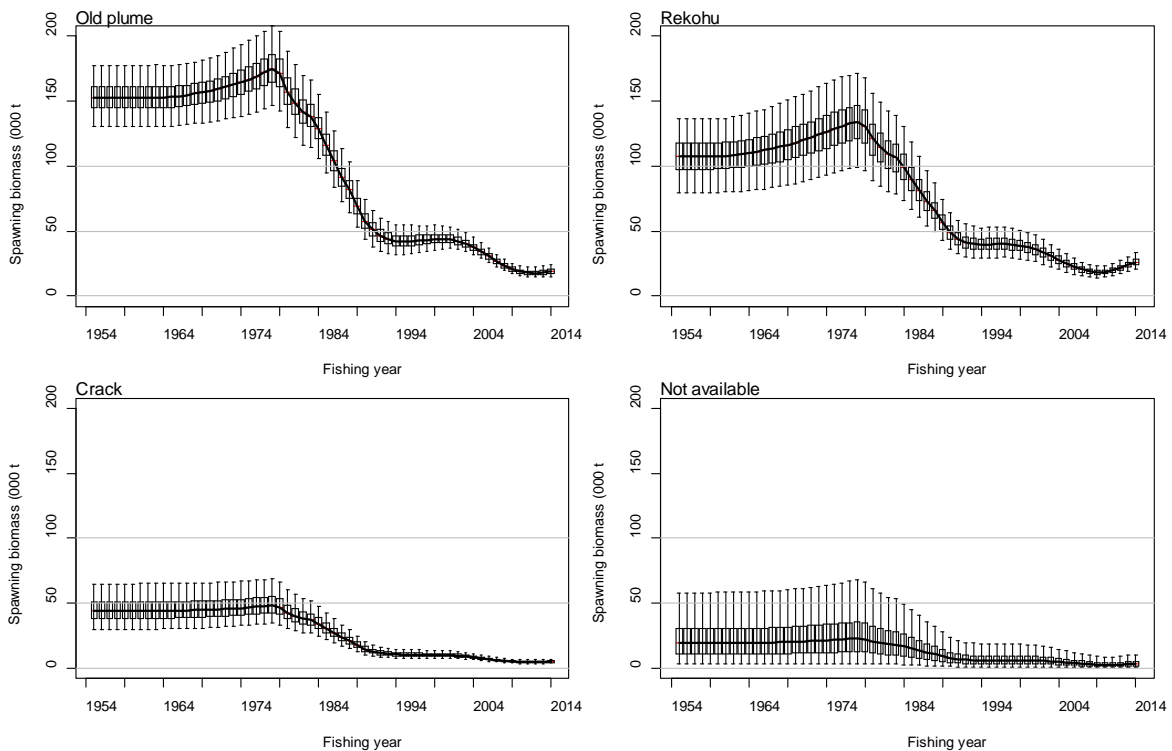

Figure 20: ESCR, MCMC: “Always” sensitivity model: spawning biomass trajectories for each area in the model including the Rekohu plume which is assumed, in this run, to have always existed. The box covers 50% of the distribution in each year and the whiskers extend to 95% of the distribution.

The sensitivities that assumed the first occurrence of the Rekohu plume in 2007 or 2010 were also critically examined to see if they were able to adequately explain the data, as well as being consistent with other ancillary information. It was found that a creation year of 2010 did not allow enough time for the Rekohu plume to build up to the levels of biomass observed in 2011 (unless fish spawning outside the three surveyed areas suddenly began joining the Rekohu plume, another assumption

thought unlikely by the DWFAWG). However, a creation year of 2007 did provide sufficient time to allow for the Rekohu plume to build up to the size observed in 2011, without the need to assume that existing spawning fish would change their spawning sites. The Rekohu 2007 model also fitted the data adequately. The Rekohu 2007 model was taken through to MCMC but it was not considered as a base model because there was no evidence to support the assumption that the Rekohu plume first occurred in 2007.

MCMC results

For the base model, MCMC convergence diagnostics were adequate once the three chains (with random starting values near the MPD estimate) had been run for 15 million iterations. These chains were much longer than those normally required and it appeared that the slow convergence was due to a high correlation between B_0 and the age at 50% maturity. Some technical changes were made to improve chain convergence; they were successful and gave identical results to the base model without the changes. The technical changes were used in the sensitivity runs to avoid running chains out to 15 million.

Virgin biomass, B_0 , was estimated to be about 320,000 t for the base model with median estimates ranging from 310,000–360,000 t for the four sensitivity runs presented (Table 9). Current stock status was similar across the base and the first two sensitivity runs (Table 9). The lower stock status when M was estimated reflects the lower estimates of M (0.036 rather than 0.045). For the two “bounding” runs, where M and the mean of the acoustic q priors were shifted by 20%, current stock status was estimated well below the biomass target range of 30–40% B_0 for the pessimistic *LowM-Highq* run and primarily within the target range for the optimistic *HighM-Lowq* run (Table 9).

Table 9: ESCR, MCMC estimates of virgin biomass (B_0) and stock status (B_{2014} as % B_0) for the base model and four sensitivity runs.

	M	B_0 (000 t)	95% CI	B_{2014} (% B_0)	95% CI
Base	0.045	320	280-350	30	25-34
Estimate M	0.036	360	300-410	26	20-32
Rekohu 2007	0.045	310	280-340	26	22-30
LowM-Highq	0.036	340	320-370	22	19-26
HighM-Lowq	0.054	310	280-350	38	32-43

Figure 21: ESCR base, MCMC estimated “true” YCS (R_y/R_0). The box in each year covers 50% of the distribution and the whiskers extend to 95% of the distribution.

The estimated YCS show little variation across cohorts but do exhibit a long-term trend (Figure 21). The most recent 10 years of estimates (those resampled for short-term projections) are a little above average.

The stock status trajectory shows a steady decline from the start of fishery until the mid 1990s where it remains in the 20-30% range until an upturn in about 2010 (Figure 22)

Figure 22: ESCR base, MCMC estimated spawning-stock biomass trajectory. The box in each year covers 50% of the distribution and the whiskers extend to 95% of the distribution. The hard limit 10% B_0 (red), soft limit 20% B_0 (blue), and biomass target range 30–40% B_0 (green) are marked by horizontal lines.

Fishing intensity was estimated in each year for each MCMC sample to produce a posterior distribution for fishing intensity by year. Fishing intensity is represented in term of the median exploitation rate and the Equilibrium Stock Depletion (ESD). For the latter, a fishing intensity of $U_{x\%B_0}$ means that fishing (forever) at that intensity will cause the SSB to reach deterministic equilibrium at x% B_0 (e.g., fishing at $U_{30\%B_0}$ forces the SSB to a deterministic equilibrium of 30% B_0). Fishing intensity in these units is plotted as 100–ESD so that fishing intensity ranges from 0 ($U_{100\%B_0}$) up to 100 ($U_{0\%B_0}$).

Estimated fishing intensity was within or above the target range ($U_{30\%B_0}$ – $U_{40\%B_0}$) for most of the history of the fishery; it has been below the target range since 2010 (Figure 23).

ORANGE ROUGHY (ORH 3B)

Figure 23: ESCR base, MCMC estimated fishing-intensity trajectory. The box in each year covers 50% of the distribution and the whiskers extend to 95% of the distribution. The fishing-intensity range associated with the biomass target of 30–40% B_0 is marked by horizontal lines.

Biological reference points, management targets and yield

MCMC estimates of deterministic B_{MSY} and associated values were produced for the base model. The yield at 35% B_0 (the mid-point of the target range) was also estimated. There is little variation in the reference points and associated values across the MCMC samples (Table 10).

There are several reasons why deterministic B_{MSY} is not a suitable target for use in fisheries management. First, it assumes a harvest strategy that is unrealistic in that it involves perfect knowledge (current biomass must be known exactly in order to calculate the target catch) and annual changes in TACC (which are unlikely to happen in New Zealand and not desirable for most stakeholders). Second, it assumes perfect knowledge of the stock-recruit relationship, which is often poorly known. Third, it would be very difficult with such a low biomass target to avoid the biomass occasionally falling below 20% B_0 , the default soft limit according to the Harvest Strategy Standard.

Table 10: ESCR base, MCMC estimates of deterministic equilibrium SSB and long-term yield (% B_0 and tonnes) for U_{MSY} and $U_{35\%B_0}$. The equilibrium SSB at U_{MSY} is deterministic B_{MSY} and the yield is deterministic MSY .

Fishing intensity		SSB (% B_0)	Yield (% B_0)	Yield (t)
U_{MSY}	Median	21.8	2.4	7716
	95% CI	20.2-23.4	2.3-2.7	7264–8237
$U_{35\%B_0}$	Median	35.0	2.3	7175
	95% CI		2.1-2.5	6740–7666

Projections

Five year projections were conducted (with resampling from the last 10 estimated YCS) for two different constant catch assumptions: 3100 t (the current catch limit); and 6400 t (the current estimated yield at $U_{35\%B_0}$). In each case a 5% catch over-run was assumed. Projections were done for the base model and also for the LowM-Highq model (as a “worst case” scenario).

At the current catch limit (3100 t), SSB is predicted to increase steadily over the next five years for both models (Figure 24). At the catch associated with $U_{35\%B_0}$ (6400 t), SSB is predicted to rise slightly for both models (Figure 24). For both models and both constant catch scenarios the estimated probability of SSB going below the hard limit is zero over the next five years. There is also zero probability for the base model of going below 20% B_0 under either catch scenario. For the LowM-Highq model there is a small but non-zero probability that the SSB is already below 20% in 2014 but this decreases over time for both catch scenarios (Figure 24).

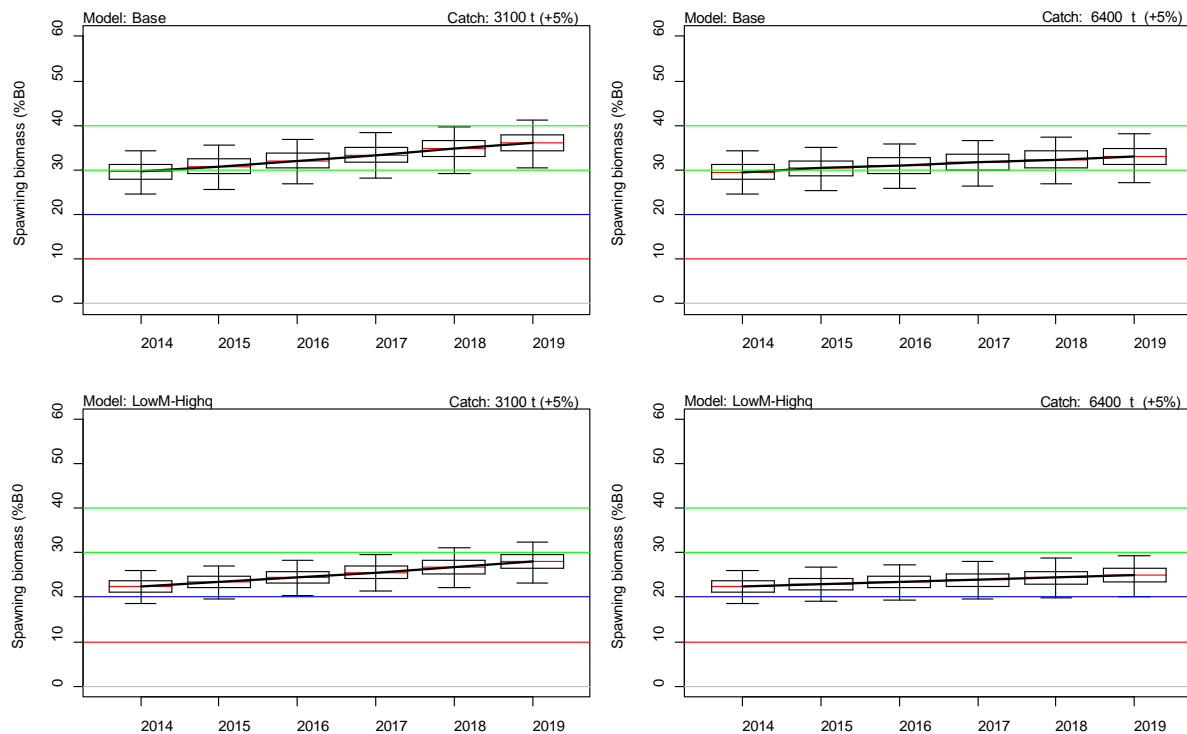

Figure 24: ESCR base, MCMC projections. The box in each year covers 50% of the distribution and the whiskers extend to 95% of the distribution. The projections are for the model and annual catch indicated (a 5% catch over-run was included in each year). The 30–40% B_0 target range is indicated by horizontal green lines and the hard limit 10% B_0 and soft limit 20% B_0 by red and blue lines respectively.

5. STATUS OF THE STOCKS

For orange roughy stocks, the management target is a biomass range from 30–40% B_0 .

5.1 Chatham Rise

Stock Structure Assumptions

Chatham Rise orange roughy are believed to comprise two biological stocks; these are assessed and managed separately: one on the Northwest of the Chatham Rise and the other ranging throughout the East and South Rise. This assumed stock structure is based on the presence of two main areas where spawning takes place simultaneously, and observed and inferred migration patterns of adults and juveniles. These two biological stocks form the bulk of the ORH 3B Fishstock. They are geographically separated from all other ORH 3B biological stocks.

Northwest Chatham Rise

Stock Status	
Year of Most Recent Assessment	2014
Assessment Runs Presented	Base model only
Reference Points	Management Target: Biomass range 30–40% B_0 Soft Limit: 20% B_0 Hard Limit: 10% B_0 Overfishing threshold: Fishing intensity range $U_{30\%B_0}$ – $U_{40\%B_0}$
Status in relation to Target	B_{2014} was estimated at 37% B_0 . Likely (> 60%) to be at or above the lower end of the management target range
Status in relation to Limits	B_{2014} is Very Unlikely (< 10%) to be below the Soft Limit B_{2014} is Exceptionally Unlikely (< 1%) to be below the Hard Limit
Status in relation to Overfishing	Fishing intensity in 2014 was estimated at $U_{89\%B_0}$ Overfishing is Exceptionally Unlikely (< 1%) to be occurring

Historical Stock Status Trajectory and Current Status

Historical trajectory of spawning biomass (% B_0), median exploitation rate (%) and fishing intensity (100-ESD) (base model, medians of the marginal posteriors). The biomass target range of 30-40 % B_0 and the corresponding exploitation rate range are marked in green. The soft limit (20% B_0) is marked in blue and the hard limit (10% B_0) in red. Note that the Y-axis is non-linear.

Fishery and Stock Trends	
Recent Trend in Biomass or Proxy	Biomass reached its lowest point in 2004 and has increased consistently since then. According to the Harvest Strategy Standard, the stock is now considered to be fully rebuilt (at least a 70% probability that the lower end of the management target range of 30–40% B_0 has been achieved).
Recent Trend in Fishing Intensity or Proxy	Fishing intensity decreased sharply from 2010 to 2011 and has remained well below the overfishing threshold since then.
Other Abundance Indices	-
Trends in Other Relevant Indicators or Variables	-

Projections and Prognosis	
Stock Projections or Prognosis	Biomass is expected to increase or stay steady over the next 5 years at annual catches of up to 1400 t.

Probability of Current Catch or TACC causing Biomass to remain below or to decline below Limits	At both current catch (110 t) or current catch limit (750 t): Soft Limit: Very Unlikely (< 10%) Hard Limit: Exceptionally Unlikely (< 1%)
Probability of Current Catch or TACC causing Overfishing to continue or to commence	At current catch: Exceptionally Unlikely (< 1%) At current catch limit: Very Unlikely (< 10%)

Assessment Methodology and Evaluation		
Assessment Type	Level 1 - Full quantitative stock assessment	
Assessment Method	Age-structured CASAL model with Bayesian estimation of posterior distributions	
Assessment Dates	Latest assessment: 2014	Next assessment: unknown
Overall assessment quality rank	1 – High Quality	
Main data inputs (rank)	-Acoustic estimates of spawning biomass on Graveyard (1999, 2012-13) and Morgue (1999, 2012). -Trawl survey age frequency and proportion-spawning-at-age (1994). -17 years of length frequency data.	1 – High Quality 1 – High Quality 1 – High Quality
Data not used (rank)	-CPUE -Trawl surveys of hills (1990-2002) -Wide-area acoustic survey estimates -Chatham Rise trawl survey deepwater stations (2010-2014) -Egg survey estimate	3 – Low Quality: unlikely to be indexing stock-wide abundance 3 – Low Quality: unlikely to be indexing stock-wide abundance 2 – Medium or Mixed Quality: large potential bias due to mixed-species 2 – Medium or Mixed Quality: variable indices 3 – Low Quality: survey design assumptions not met
Changes to Model Structure and Assumptions	The previous assessment was in 2006. -Model now based on spawning biomass rather than transition-zone mature biomass. -Age data included to enable estimation of year class strengths rather than assuming deterministic recruitment. - A more stringent data quality threshold was imposed on data inputs (e.g., CPUE indices not used, egg survey and wide-area acoustic estimates also excluded).	
Major Sources of Uncertainty	-The largest source of uncertainty is the proportion of the NWCR spawning stock that is indexed by the acoustic survey in each year. -Patterns in year class strengths are based on only one year of age composition data. -The time series of abundance indices is short and restricted to the period of lower stock status.	

ORANGE ROUGHY (ORH 3B)

Qualifying Comments

Estimates of stock biomass are sensitive to the means of the q priors. In addition, when higher CVs were used for the informed acoustic q priors, the median estimates of biomass and stock status were slightly higher and the confidence intervals were wider with a much higher upper bound.

Fishery Interactions

Main bycatch species are smooth oreo, black oreo, rattails, deepwater dogfish and hoki, with lesser bycatches of Johnson’s cod and ribaldo. Low productivity bycatch species include deepwater sharks, skates and corals. Overall, bycatch usually comprises about 20% of the total catch. Observed incidental captures of protected species include corals, low numbers of seabirds and occasional NZ fur seals.

East and South Chatham Rise

Stock Status

Year of Most Recent Assessment	2014
Assessment Runs Presented	Base model only
Reference Points	Management Target: Biomass range 30–40% B_0 Soft Limit: 20% B_0 Hard Limit: 10% B_0 Overfishing threshold: Fishing intensity range $U_{30\%B_0}$ – $U_{40\%B_0}$
Status in relation to Target	B_{2014} was estimated to be 30% B_0 About as Likely as Not (40–60%) to be at or above the lower end of the management target range
Status in relation to Limits	B_{2014} is Unlikely (< 40%) to be below the Soft Limit B_{2014} is Very Unlikely (< 10%) to be below the Hard Limit
Status in relation to Overfishing	Fishing intensity in 2014 was estimated at $U_{52\%B_0}$ Overfishing is Very Unlikely (< 10%) to be occurring

Historical Stock Status Trajectory and Current Status

Historical trajectory of spawning biomass (% B_0), median exploitation rate (%) and fishing intensity (100-ESD) (base model, medians of the marginal posteriors). The biomass target range of 30-40 % B_0 and the corresponding exploitation rate range are marked in green. The soft limit (20% B_0) is marked in blue and the hard limit (10% B_0) in red. Note that the Y-axis is non-linear.

Fishery and Stock Trends	
Recent Trend in Biomass or Proxy	The spawning biomass is estimated to have been slowly increasing over the last four years.
Recent Trend in Fishing Intensity or Proxy	Fishing intensity (exploitation rate) is estimated to have been below the lower end of the target range in the last four years.
Other Abundance Indices	-
Trends in Other Relevant Indicators or Variables	-

Projections and Prognosis	
Stock Projections or Prognosis	Biomass is expected to increase or stay steady over the next 5 years at annual catches of up to 6400 t.
Probability of Current Catch or TACC causing Biomass to remain below or to decline below Limits	At current catch or catch limit (3100 t) Soft Limit: Unlikely (< 40%) Hard Limit: Very Unlikely (< 10%)

Assessment Methodology and Evaluation		
Assessment Type	Level 1 - Full quantitative stock assessment	
Assessment Method	Age-structured CASAL model with Bayesian estimation of posterior distributions	
Assessment Dates	Latest assessment: 2014	Next assessment: 2015
Overall assessment quality rank	1 – High Quality	
Main data inputs (rank)	-Four short time series of biomass indices from research trawl surveys -Acoustic indices from research surveys of spawning plumes (Old-plume, Rekohu plume, Crack) -Age frequencies from the spawning plumes in 2012 and 2013 -Length frequencies from commercial fisheries	1 – High Quality 1 – High Quality 1 – High Quality 1 – High Quality
Data not used (rank)	-CPUE -Acoustic surveys of hills (hull-mounted transducers) -Wide-area acoustic survey estimates -CR deepwater trawl survey stations (2010-2014)	3 – Low Quality: unlikely to be indexing stock-wide abundance 3 – Low Quality: major species identification and dead zone issues 2 – Medium or Mixed Quality: large potential bias due to mixed-species 2 – Medium or Mixed Quality: variable indices
Changes to Model Structure and Assumptions	The most recent model-based assessment was in 2006. Subsequent assessments have been based on an expert assessment of data, principally acoustic biomass estimates. -The current assessment is fully quantitative and based on spawning biomass rather than transition-zone mature biomass. -Age data have been included to enable estimation of year class strengths rather than assuming deterministic recruitment. - A more stringent data quality threshold was imposed on data	

ORANGE ROUGHY (ORH 3B)

	inputs (e.g. CPUE indices and wide-area acoustic estimates not used)
Major Sources of Uncertainty	<ul style="list-style-type: none">-The largest source of uncertainty is the proportion of the ESCR spawning stock that is indexed by the acoustic survey in each year.-Stock status is dependent on the timing of the appearance of the Rekohu spawning plume, which is unknown.-Patterns in year class strengths are based on only 2 years of age composition data.

Qualifying Comments

-Estimates of stock biomass are sensitive to the means of the q priors. In addition, when higher CVs were used for the informed acoustic q priors, the median estimates of biomass and stock status were slightly higher and the confidence intervals were wider with a much higher upper bound.

-There were some concerns about a potential lack of convergence in the MCMCs.

Fishery Interactions

Main bycatch species are smooth oreo, black oreo, deepwater dogfish, hoki and rattails, with lesser bycatches of slickhead, Johnson's cod and morids. Low productivity bycatch species include deepwater sharks and dogfish and also corals. Overall, bycatch usually comprises about 25% of the total catch, the majority of which are QMS species. Observed incidental captures of protected species include corals, low numbers of seabirds and occasional NZ fur seals.

5.2 Southern ORH 3B fisheries

Puysegur

The 1998 assessment for this stock (Annala et al 1998) was uncertain because the three time series of biomass indices on which it was based are all very short. However, all three series (two of trawl surveys and one of CPUE) suggested that the biomass was reduced substantially up to 1998. The point estimate of biomass from this assessment was probably below B_{MSY} , but it was uncertain. Estimates of MCY and CAY were 420 t or less. The fishery was voluntarily closed in 1997–98 in order to maximise the rate of rebuilding. It was re-opened in 2010–11 with a catch limit of 150 t (Table 3).

Auckland Islands (Pukaki South)

The Deepwater Working Group examined the data on orange roughy catch and effort from the Auckland Islands area in 2006, and found that there had been relatively little fishing activity in this area in the previous few years. There were insufficient data to conduct a standardised CPUE analysis, and it was believed that unstandardised CPUE did not provide a suitable index of relative abundance. Therefore, a stock assessment could not be carried out.

Other fisheries

In 2006 the Deepwater Working Group examined the data on orange roughy catch and effort from other parts of ORH 3B – the Bounty Islands, Pukaki Rise, Snares Island and the Arrow Plateau – and agreed that there were insufficient data to carry out standardised CPUE analyses for any of these areas.

ORANGE ROUGHY CHALLENGER PLATEAU (ORH 7A)

1. FISHERY SUMMARY

1.1 Commercial fisheries

Historically, the fishery mainly occurred in the south-western region of the Challenger Plateau, both inside and outside the EEZ. Fish were caught throughout the year, with most effort in winter when the orange roughy form aggregations for spawning. Domestic vessels caught most of the quota. Total catches peaked at 10 000–12 000 t annually from 1986–87 to 1988–89 (Table 1). Total catch and ORH 7A catch were less than 2100 t annually from 1990–91 until the closure in 2000–01 (Table 1, Figure 1), when the TACC for this stock was reduced to 1 t.

Recent surveys have shown an increase in biomass in the area. On 1 October 2010 the TACC was increased from 1 t to 500 t, with a 25 t allowance for other mortality, raising the TAC to a total of 525 t.

Table 1: Reported catches (t) and TACs (t) from 1980–81 to 2012–13. QMS data from 1986-present.

†FSU data

*This is a minimum value, because of unreported catches by foreign vessels fishing outside the EEZ.

+Unknown distribution of catch between inside and outside the EEZ

Catches taken during winter trawl and acoustic surveys were approximately 200 t each year.

1.2 Recreational fisheries

There is no known recreational fishing for orange roughy in this area.

1.3 Customary non-commercial fisheries

There is no known customary non-commercial fishing for orange roughy in this area.

1.4 Illegal catch

There is no quantitative information available on illegal catch.

ORANGE ROUGHY (ORH 7A)

Figure 1: Historical reported landings and TACC for ORH 7A. Note that this figure does not show data prior to entry into the QMS.

1.5 Other sources of mortality

In previous stock assessments, catch overruns from various sources (including lost and/or discarded fish, use of nominal tray weights and low conversion factors) have been estimated as: 1980–81 to 1987–88, 30%; 1988–89, 25%; 1989–90, 20%; 1990–91, 15%; 1991–92 to 1992–93, 10%; 1993–94 onwards, 5%.

2. BIOLOGY

Biological parameters used in this assessment are presented in the Biology section at the beginning of the Orange Roughy Introduction section.

3. STOCKS AND AREAS

There is no new information on orange roughy stock structure beyond that presented in previous assessment documents.

Orange roughy on the southwest Challenger Plateau (Area 7A, including Westpac Bank) are regarded as a single separate stock. Size structure, parasite composition, flesh mercury levels, allozyme frequency and mitochondrial DNA studies show differences to other major fisheries. Spawning occurs at a similar time to fish on the Chatham Rise, Puysegur Bank, Ritchie Banks, Cook Canyon and Lord Howe Rise.

4. STOCK ASSESSMENT

A model-based Bayesian stock assessment was carried out for this stock in 2014. It was the first model-based assessment since 2005 (MFish 2006) when a Bayesian model was used to update the 2000 assessment (Annala et al 2000, Field & Francis 2001). From 2010 to 2013, assessments were conducted using an ad hoc approach which combined the virgin biomass estimate from the 2000 assessment and current biomass estimates from annual combined acoustic and trawl surveys (see Clark et al 2006, NIWA & FRS 2009, Doonan et al 2010, Hampton et al 2012, Hampton et al 2013, Cordue 2010, 2012, 2013).

The 2014 assessment for this stock was one of four orange roughy assessments carried out in 2014 which all used similar methods (see Orange Roughy Introduction). An age-structured population model was fitted to combined acoustic and trawl-survey estimates of spawning biomass, two trawl-survey time series of spawning biomass, and three trawl-survey age frequencies.

4.1 Model structure

The model was single-sex and age-structured (1-100 years with a plus group), with maturity estimated separately (i.e., fish were classified by age and as mature or immature). Two time steps were used: a full year of natural mortality followed by an instantaneous spawning season and fishery on the spawning fish. The fishery selectivity was uniform across ages (for spawning fish) and 100% of mature fish were assumed to spawn each year.

The catch history was constructed from the total catches in Table 1 and the over-run percentages in Section 1.5. Natural mortality was assumed to be fixed at 0.045 and the stock-recruitment relationship was assumed to follow a Beverton-Holt function with steepness of 0.75. The remaining fixed biological parameters are given in the Orange Roughy Introduction.

4.2 Input data and statistical assumptions

There were three main data sources for observations fitted in the assessment: spawning biomass estimates from combined acoustic and trawl surveys (2006, 2009–2013); an early trawl survey time series of relative spawning biomass (1987–1989); and three age frequencies from the trawl surveys (1987, 2006, and 2009).

4.2.1 Research surveys

Trawl surveys of orange roughy on the Challenger Plateau were conducted regularly from 1983 to 1990. However, a variety of vessels and survey strata were used which makes comparisons problematic (Dunn et al 2010). Wingtip biomass estimates in 1983–1986 ranged from 100 000–185 000 t but the 1989 and 1990 survey estimates much lower at approximately 10 000 t. From these early trawl surveys a “comparable area” time series, defined by Clark & Tracey (1994) and covering the period 1987–89, was selected for use in the assessment to provide some information on the early rate of spawning biomass decline (Table 2).

In 2005, a new series of combined trawl and acoustic surveys was begun using the *FV Thomas Harrison* with a survey area comparable to that used from 1987–1990 (Clark et al 2005). The survey was repeated in 2006 (with an enlarged survey area) and was then conducted annually from 2009–2013 (Clark et al 2006, NIWA & FRS 2009, Doonan et al 2010, Hampton et al 2012, Hampton et al 2013). It was apparent from the later surveys that the 2005 survey did not cover an appropriate area as the spawning biomass distribution had shifted somewhat in the intervening years. The surveys from 2006 onwards appear to have covered the bulk of the spawning biomass. The data from these surveys have been analysed to produce three types of indices used in this assessment: combined acoustic and trawl survey spawning biomass; acoustic estimates of spawning plumes; trawl survey indices of spawning biomass.

Combined acoustic and trawl survey indices

The method of Cordue (2010, 2012) was used to produce combined acoustic and trawl survey indices for 2010 and 2013 (Table 2). This method used an estimate of orange roughy trawl vulnerability to allow the trawl survey estimates to be combined with the acoustic estimates (trawl estimates are essentially scaled down by a vulnerability distribution with a mean of 1.66). The method accounts for observation error and potential bias in orange roughy target strength by combining priors and “error distributions” centred on the observations (Cordue 2010, 2012). Strata 9-11 were excluded from the estimates as they covered hills and/or very rough terrain (i.e., were not included because orange roughy are probably not equally vulnerable to the trawl gear on the hills and on the flat).

The 2010 and 2013 surveys were used in this way for different reasons. In 2010, the survey specifically excluded spawning plumes from the trawl survey strata and the plumes were surveyed acoustically. In other years, plumes were not explicitly excluded from the trawl survey area and a

ORANGE ROUGHY (ORH 7A)

number of random trawl stations did obtain very high catch rates in the vicinity of plumes. The 2010 design was specifically aimed at combining the acoustic and trawl survey estimates.

The 2013 survey had three trawl stations with very high catch rates in two strata which were near where spawning plumes were surveyed. As a consequence, the trawl survey index had a very high CV of 51%. It seemed preferable to replace the trawl estimates from the two “plume” strata with the corresponding acoustic estimates and combine them with the remaining trawl estimates (following Cordue 2012) which gave a combined index with a lower CV of 35% (Table 2).

The estimates were used as relative biomass with a lognormal informed prior on the q . The total survey area was assumed to cover 90% of the spawning biomass and the three excluded strata (9-11) were estimated to account for 15% of the surveyed biomass (from years in which they were surveyed). The mean of the informed prior was therefore $0.9 \times 0.85 = 0.77$. The CV was chosen so that the CVs for the prior and the observation were equal in 2010 and the combined CV from observation error and the prior were equal to 0.3 (2010) and 0.35 (2013) (the CVs of the distribution-estimates of spawning biomass). This gave a prior CV of 0.21.

Acoustic estimate for two plumes in 2009

Two spawning plumes were acoustically surveyed on 4–5 July 2009. The main plume was covered by two snapshots and had a much higher average biomass than was seen in a comparable survey conducted during the previous few days (28 June–2 July): 16 800 t compared to 6700 t. A second plume was also surveyed with a single snapshot (6300 t) and the combined estimate was 23 100 t (Table 2). This unusual event led to the conclusion that “most” of the 2009 spawning biomass was present in the two surveyed plumes.

This was modelled by treating the acoustic estimate as relative biomass and estimating the proportionality constant (q) with an informed prior. The acoustic q prior described in the Orange Roughy Introduction was used: a mean of 0.8 (i.e., “most” = 80%) and a CV of 19%.

Trawl survey indices

The spawning biomass estimates from the *Thomas Harrison* trawl surveys in 2006, 2009–2012 (Table 2) were used as relative biomass with an informed prior. They excluded the rough terrain strata 9-11 and the mean of the informed prior was: $0.9 \times 0.85 \times 1.66 = 1.27$ (allowing for total-survey availability (0.9), exclusion of strata 9-11 (0.85) and trawl vulnerability – mean of estimated vulnerability distribution = 1.66). Given the problematic nature of these trawl surveys (fish pluming and moving within the area), a process error CV of 20% was added to the estimated CVs (Table 2).

Table 2: Biomass indices used in the stock assessment. The model CV is the observation error used in the base model. A 20% process error CV has been added to the sample CV for the trawl indices. The CV for the combined acoustics and trawl estimates has been split between the informed q -prior (CV = 21%) and the observation error in the model.

Series	Year	Biomass index (t)	CV (%)	Model CV (%)
<i>Amaltal Explorer</i>	1987	75 040	26	33
	1988	28 954	27	34
	1989	11 062	11	23
<i>Thomas Harrison</i>	2006	13 987	27	34
	2009	34 864	24	31
	2011	18 425	26	33
	2012	22 451	18	27
	2013	18 993	51	55
Acoustics & trawl	2010	14 766	30	21
	2013	13 637	35	28
Two plumes	2009	23 095	25	25

Age frequencies

Age frequencies were available from three of the trawl surveys for use in the assessment. A previous analysis produced age frequencies for the 1987 *Amaltal Explorer* survey and the 2009 *Thomas Harrison* survey (Doonan et al 2013), although that study was based on a relatively small number of otoliths, it showed that the 2009 age frequency had much younger fish than the 1987 age frequency. For the stock assessment, the existing age frequencies were augmented with an increased number of

otoliths (for a total of about 300 for each survey) and a new age frequency (from about 300 otoliths) was produced for the 2006 *Thomas Harrison* survey.

The age frequencies were assumed to be multinomial and were assigned effective sample sizes of $300/5 = 60$ (with the sample size reflecting the number of trawl stations rather than the number of otoliths).

4.3 Model runs and results

In the base model, natural mortality (M) was fixed at 0.045. There were numerous MPD sensitivity runs but three main sensitivities are presented in this report: estimate M ; and the LowM-Highq and HighM-Lowq runs (see the Orange Roughy Introduction section for specifications).

In the base model the main parameters estimated were: virgin biomass (B_0), the maturity ogive, and year class strengths (YCS) from 1925 to 1985 (with the Haist parameterisation and “nearly uniform” priors on the free parameters). There were also the proportionality constants (q) for the two trawl survey time series, the combined acoustic and trawl estimates (2010, 2013) and the two-plumes estimate in 2009.

4.3.1 Model diagnostics

The model provided good MPD fits to the biomass indices although the 2009 trawl index had a large positive residual (Figure 2, top right). The large positive residual in 2009 was balanced by negative residuals in the other years. In a sensitivity run, taken through to MCMC, the 2009 index was removed. This had no effect on the stock status estimates for the MPD or MCMC runs but it did provide an improved fit to the other biomass indices (the 2009 index is not influential in terms of important derived estimates but does affect the residual pattern). The MCMC normalised residuals for the biomass indices show a similar pattern to the MPD fit, but the only large residuals are for the *Amaltal Explorer* time series (Figure 3). The magnitude of the *Amaltal Explorer* residuals could be reduced by adding more process error, but this would not affect any of the important assessment estimates (the same results are obtained if the *Amaltal* time series is removed altogether).

The MPD fit to the age frequencies was very good (Figure 4).

The biomass indices with the informed priors are free to “move” somewhat as they are relative. The MPD estimated qs were not very different from the mean of the informed priors (Figure 5, blue dots). The same is not true for the MCMC runs, as the *Thomas Harrison* q and the combined acoustics and trawl q have both moved to the left appreciably (Figure 5, right-hand plots). Although they have moved, the posteriors are still well within the distribution of the priors, leaving the estimated qs credible.

Numerous MPD sensitivity runs were performed. These showed that the main drivers of the estimated stock status were natural mortality (M) and the means of the informed q priors (lower M and higher mean q give lower stock status; higher M and lower mean q give higher stock status). The base model was robust to changes in the relative weights of the different data sets. Large changes in estimated 2014 stock status only occurred when deterministic recruitment was assumed (49% B_0 compared to 32% B_0 for the base) or when recent biomass indices were halved or doubled (respectively 18% B_0 and 50% B_0).

ORANGE ROUGHY (ORH 7A)

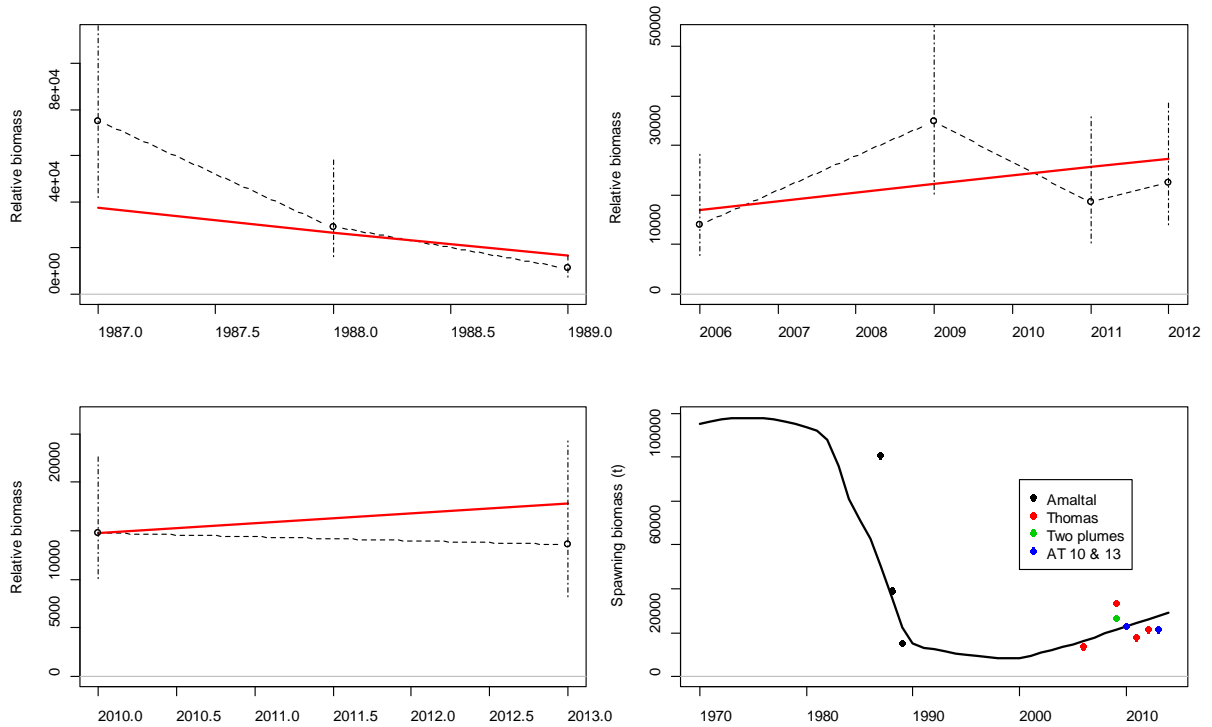

Figure 2: MPD fit to biomass indices: top left: *Amaltal Explorer*; top right: *Thomas Harrison*; bottom left: combined acoustics and trawl; bottom right: indices scaled to spawning biomass (using MPD estimated q_s). Vertical lines are 95% CIs (model CVs).

Figure 3: MCMC base: normalised residuals for the biomass indices. The box covers 50% of the distribution for each index and the whiskers extend to 95% of the distribution. “A&T” denotes combined acoustics and trawl (2010, 2013); “Amaltal” the *Amaltal Explorer* series; “Thomas” the *Thomas Harrison* series; and “Plumes” the two-plumes estimate from 2009.

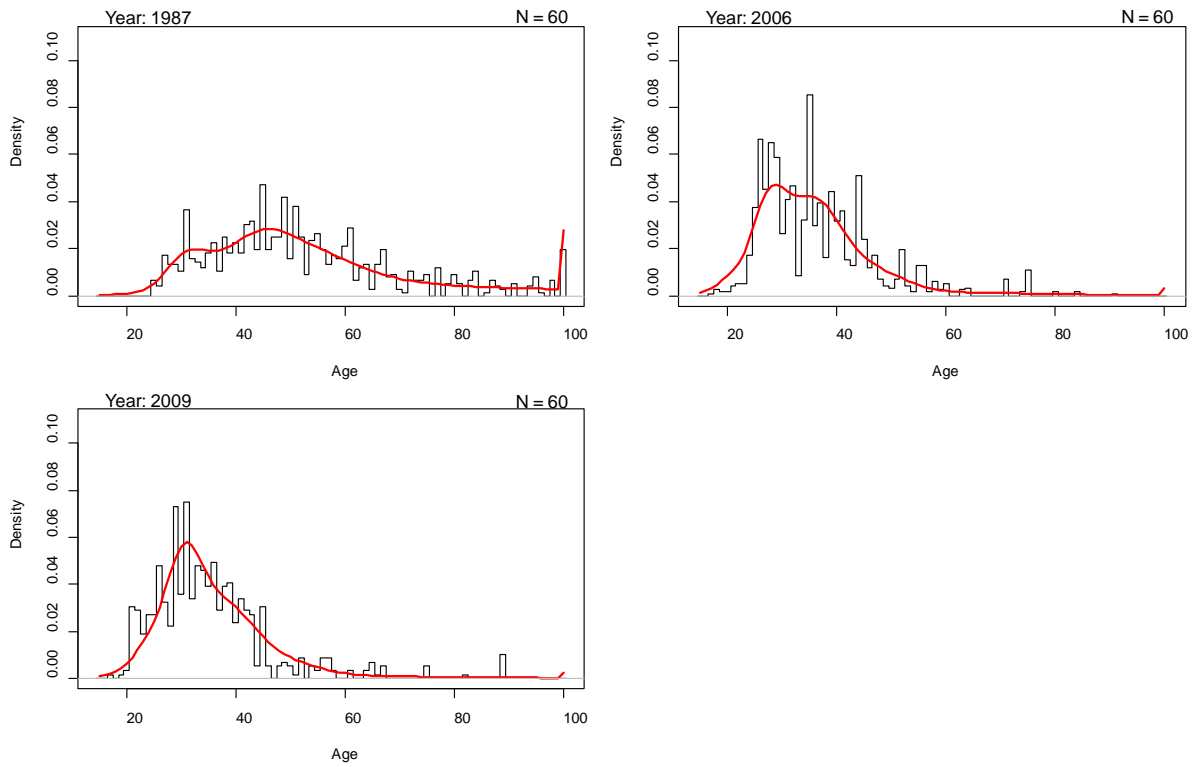

Figure 4: MPD fit to spawning-season trawl-survey age frequencies for the 1987, 2006 and 2009 surveys (N = 60 is the assumed effective sample size). Observations are square-topped black lines; model predictions are the smooth red lines.

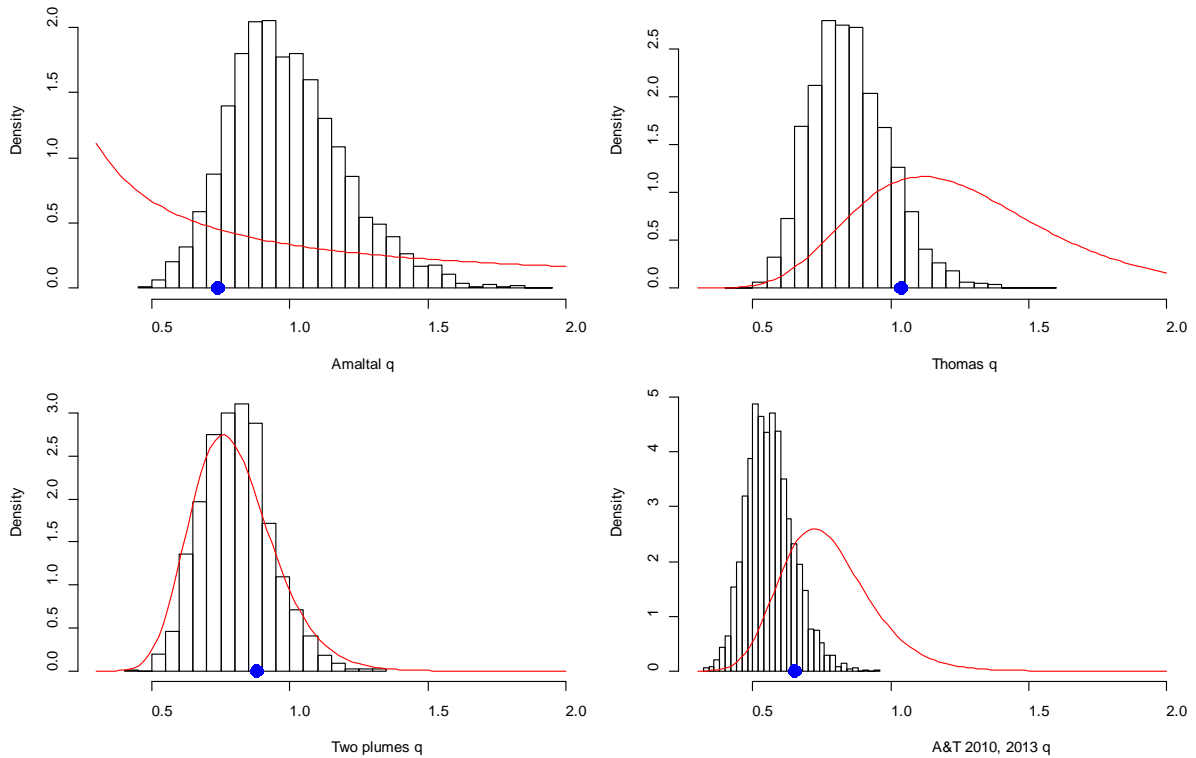

Figure 5: Base model MCMC diagnostics: prior and posterior distributions for the biomass time series q_s (prior in red, posterior black histograms; the blue dot is the MPD estimate. “Amaltal q” denotes the *Amaltal Explorer* series; “Thomas q” the *Thomas Harrison* series; “Two plumes q” the two-plumes estimate from 2009; and “A&T 2010, 2013 q” denotes combined acoustics and trawl for those years).

MCMC results

For the base model, and the sensitivity runs, MCMC convergence diagnostics were excellent. Virgin biomass (B_0) was estimated to be about 90 000 t for all runs (Table 3). Current stock status was similar for the base and the estimate- M run (Table 3). The slightly lower stock status when M was estimated reflects the lower estimate of M (0.039 rather than 0.045). For the two runs, where M and the mean of the informed q priors were shifted either up or down by 20%, median current stock status was estimated within the biomass target range of 30–40% B_0 for the *LowM-Highq* run but well above the range for the *HighM-Lowq* run (Table 3).

Table 3: MCMC estimates of virgin biomass (B_0) and stock status (B_{2014} as % B_0) for the base model and three sensitivity runs.

	M	B_0 (000 t)	95% CI	B_{2014} (% B_0)	95% CI
Base	0.045	88	82-96	42	35-49
Estimate M	0.039	92	84-100	38	30-47
LowM-Highq	0.036	90	85-97	33	27-40
HighM-Lowq	0.054	88	81-97	51	44-59

The estimated YCS show little variation across cohorts but exhibit a long-term trend (Figure 6). The most recent 10 years (1976–1985) of estimates (those resampled for short-term projections) are about average.

Figure 6: Base, MCMC estimated “true” YCS (R_y/R_0). The box in each year covers 50% of the distribution and the whiskers extend to 95% of the distribution.

The stock status trajectory showed a steep decline to about 10% B_0 in 1990, reflecting the large removals during the initial fish-down phase of this fishery (Figure 7). From 1990 stock status remained at about 10% B_0 until a strong upturn in 2000 (Figure 7). Rebuilding has taken only 14 years to reach the top of the 30-40% biomass target range because the fishery was closed in 2001 and reopened in 2011, with relatively limited catches since then (see Table 1).

For the base model, the stock is now considered to be fully rebuilt according to the Harvest Strategy Standard (at least a 70% probability that the lower end of the management target range of 30–40% B_0 has been achieved).

Figure 7: Base, MCMC estimated spawning-stock biomass trajectory. The box in each year covers 50% of the distribution and the whiskers extend to 95% of the distribution. The hard limit 10% B_0 (red), soft limit 20% B_0 (blue), and biomass target range 30–40% B_0 (green) are marked by horizontal lines.

Fishing intensity was estimated in each year for each MCMC sample to produce a posterior distribution for fishing intensity by year. Fishing intensity is represented in term of the median exploitation rate and the Equilibrium Stock Depletion (ESD). For the latter, a fishing intensity of $U_{x\%B_0}$ means that fishing (forever) at that intensity will cause the SSB to reach deterministic equilibrium at x% B_0 (e.g., fishing at $U_{30\%B_0}$ drives the SSB to a deterministic equilibrium of 30% B_0). Fishing intensity in these units is plotted as 100–ESD so that fishing intensity ranges from 0 ($U_{100\%B_0}$) up to 100 ($U_{0\%B_0}$).

Estimated fishing intensity was within or above the target range ($U_{30\%B_0}$ – $U_{40\%B_0}$) up until the closure of the fishery in 2001. Since then, it has been well below the target range (Figure 8).

Figure 8: Base, MCMC estimated fishing-intensity trajectory. The box in each year covers 50% of the distribution and the whiskers extend to 95% of the distribution. The fishing-intensity range associated with the biomass target of 30–40% B_0 is marked by horizontal lines.

Biological reference points, management targets and yield

MCMC estimates of deterministic B_{MSY} and associated values were produced for the base model. The yield at 35% B_0 (the mid-point of the target range) was also estimated. There is little variation in the reference points and associated values across the MCMC samples (Table 4).

There are several reasons why deterministic B_{MSY} is not a suitable target for use in fisheries management. First, it assumes a harvest strategy that is unrealistic in that it involves perfect knowledge (current biomass must be known exactly in order to calculate the target catch) and annual changes in TACC (which are unlikely to happen in New Zealand and not desirable for most stakeholders). Second, it assumes perfect knowledge of the stock-recruit relationship, which is often poorly known. Third, it would be very difficult with such a low biomass target to avoid the biomass occasionally falling below 20% B_0 , the default soft limit according to the Harvest Strategy Standard.

Table 4: Base, MCMC estimates of deterministic equilibrium SSB and long-term yield (% B_0 and tonnes) for U_{MSY} and $U_{35\%B_0}$. The equilibrium SSB at U_{MSY} is deterministic B_{MSY} and the yield is deterministic MSY.

Fishing intensity		SSB (% B_0)	Yield (% B_0)	Yield (t)
U_{MSY}	Median	24.5	2.1	1853
	95% CI	22.9-24.9	2.1-2.1	1728–2009
$U_{35\%B_0}$	Median	35.0	2.0	1764
	95% CI	35.0-35.0	2.0-2.0	1645–1912

The estimate of long-term yield associated with $U_{35\%B_0}$ for the 2014-15 fishing year is 2128 t (95% CI 1673–2694 t).

Projections

Five-year projections were conducted (with resampling from the last 10 estimated YCS, 1976–1985) for two different constant catch assumptions: 500 t (the current TACC); and 2100 t (the current estimated yield at $U_{35\%B_0}$). In each case a 5% catch over-run was assumed. Projections were done for the base model and for the *LowM-Highq* sensitivity model (as a “worst case” scenario).

At the current TACC (500 t), SSB is predicted to increase steadily over the next five years for both models (Figure 9). At the catch associated with $U_{35\%B_0}$ (2100 t), SSB is predicted to decrease slightly for both models (Figure 9). For both models and both constant catch scenarios the estimated probability of SSB going below either the soft limit (20% B_0) or hard limit (10% B_0) is zero. For the *LowM-Highq* model there is a small probability (1.5% and 3% respectively) of the SSB falling below 20% B_0 in 2018 or 2019 under a 2100 t catch (Figure 9).

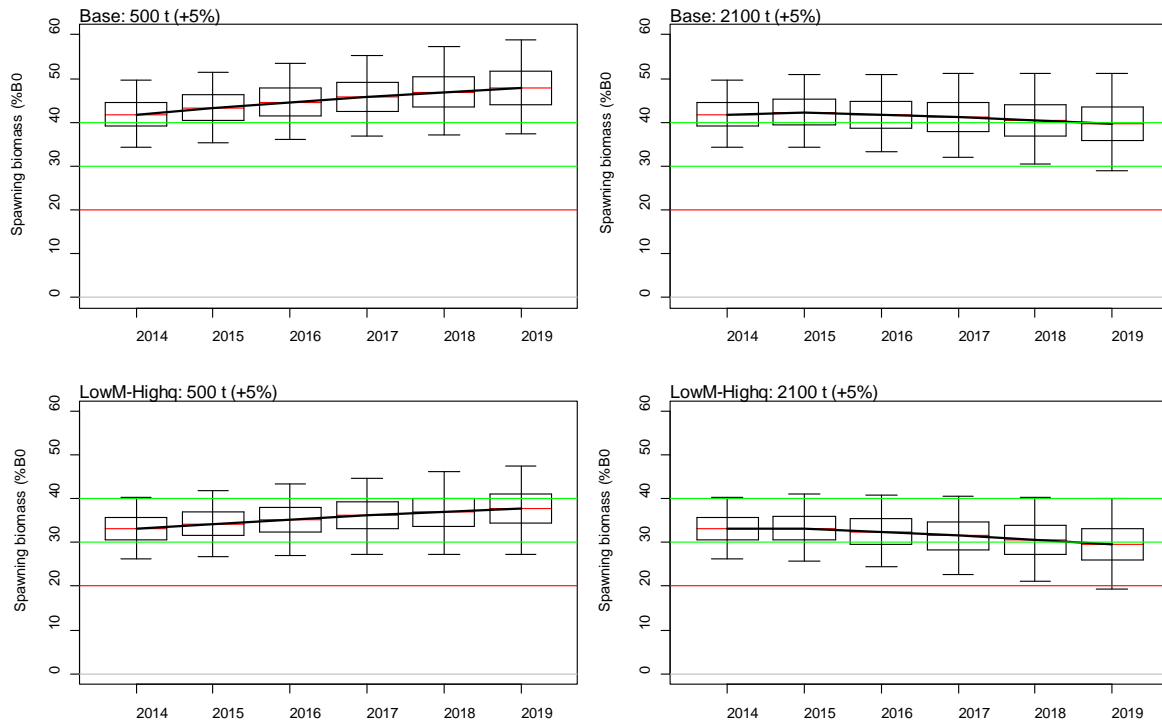

Figure 9: Base, MCMC projections. The box in each year covers 50% of the distribution and the whiskers extend to 95% of the distribution. The projections are for the model and annual catch indicated (a 5% catch over-run was included in each year). The target biomass range(30–40% B_0) is indicated by horizontal green lines, the hard limit (10% B_0) by a red line and the soft limit (20% B_0) by a blue line.

5. STATUS OF THE STOCK

Orange roughy on the southwest Challenger Plateau (Area 7A, including Westpac Bank) are regarded as a single separate stock.

Stock Status	
Year of Most Recent Assessment	2014
Assessment Runs Presented	Base model only
Reference Points	Management Target: Biomass range 30–40% B_0 Soft Limit: 20% B_0 Hard Limit: 10% B_0 Overfishing threshold: Fishing intensity range $U_{30\%B_0} - U_{40\%B_0}$
Status in relation to Target	B_{2014} was estimated to be 42% B_0 Very Likely (> 90%) to be at or above the lower end of the management target range and About as Likely as Not (40–60%) to be at or above the upper end of the management target range
Status in relation to Limits	B_{2014} is Very Unlikely (< 10%) to be below the Soft Limit B_{2014} is Exceptionally Unlikely (< 1%) to be below the Hard Limit
Status in relation to Overfishing	Fishing intensity in 2014 was estimated at $U_{71\%B_0}$ Overfishing is Very Unlikely (< 10%) to be occurring

Historical Stock Status Trajectory and Current Status

Historical trajectory of spawning biomass ($%B_0$), median exploitation rate (%) and fishing intensity (100-ESD) (base model, medians of the marginal posteriors). The biomass target range of 30-40% B_0 and the corresponding exploitation rate (fishing intensity) range are marked in green. The soft limit (20% B_0) is marked in blue and the hard limit (10% B_0) in red. Note that the Y-axis is non-linear.

Fishery and Stock Trends

Recent Trend in Biomass or Proxy	The spawning biomass is estimated to have been steadily increasing since just before the fishery closure in 2000–2001. According to the Harvest Strategy Standard, the stock is now considered to be fully rebuilt (at least a 70% probability that the lower end of the management target range of 30–40% B_0 has been achieved).
Recent Trend in Fishing Intensity or Proxy	The fishery was closed in 2000-01 and re-opened in 2010-11, with fisheries surveys conducted since 2005. Fishing intensity has been low and fairly constant since 2010-11.
Other Abundance Indices	-
Trends in Other Relevant Indicators or Variables	-

Projections and Prognosis

Stock Projections or Prognosis	Biomass is expected to increase at the current TACC (500 t) or decrease slightly over the next 5 years at annual catches of up to 2100 t.
Probability of Current Catch or TACC causing Biomass to remain below, or to decline below, Limits	Soft Limit: Very Unlikely (< 10%) Hard Limit: Exceptionally Unlikely (< 1%)
Probability of Current Catch or TACC causing Overfishing to continue or to commence	Very Unlikely (< 10%)

Assessment Methodology and Evaluation

Assessment Type	Level 1 - Full quantitative stock assessment
-----------------	--

Assessment Method	Age-structured CASAL model with Bayesian estimation of posterior distributions	
Assessment Dates	Latest assessment: 2014	Next assessment: Unknown
Overall assessment quality rank	1 – High Quality	
Main data inputs (rank)	-Combined acoustic and trawl survey estimates of spawning biomass (2010, 2013) -Acoustic survey estimate of spawning biomass from two plumes in 2009 -Two trawl survey time series: 1987-1989 and 2006, 2009-2012 -Age frequencies from the trawl surveys in 1987, 2006, and 2009	1 – High Quality 1 – High Quality 1 – High Quality 1 – High Quality
Data not used (rank)	-CPUE -Acoustic surveys of hills (hull-mounted transducers) -Early trawl surveys with different vessels covering different areas	3 – Low Quality: unlikely to be indexing stock-wide abundance 2 – Medium or Mixed Quality: species identification and dead zone problems 2 – Medium or Mixed Quality: not a consistent time series
Changes to Model Structure and Assumptions	-The previous model-based assessment was in 2005. Recent assessments have been based on an ad hoc method. -The current assessment is fully quantitative and based on spawning biomass rather than transition-zone mature biomass. -Age data were included to enable estimation of year class strengths rather than assuming deterministic recruitment. - A more stringent data quality threshold was imposed on data inputs (e.g. CPUE indices were not used).	
Major Sources of Uncertainty	-The proportion of the stock that is indexed by the combined acoustic and trawl survey. -Patterns in year class strengths are based on only 3 years of age composition data.	

Qualifying Comments

- Estimates of stock biomass are sensitive to the means of the q priors. In addition, when higher CVs were used for the informed acoustic q priors, the median estimates of biomass and stock status were slightly higher and the confidence intervals were wider with a much higher upper bound.

Fishery Interactions

Historically, the main bycatch species were deepwater dogfish, spiky oreos and ribaldo. Since the fishery re-opened with a low level of catch and effort and fishing during the spawning season, bycatch levels have been relatively low at about 4%. The bycatch of low productivity species includes deepwater sharks, deepsea skates and corals. With limited fishing effort, there have been no observed incidental captures of protected species other than corals since 2002–03.

ORANGE ROUGHY WEST COAST SOUTH ISLAND (ORH 7B)

1. FISHERY SUMMARY

1.1 Commercial fisheries

From 1 October 2007 the TACC for this stock was reduced to 1 t. Previously the fishery was centred on an area near the Cook Canyon in statistical areas 033, 034 and 705. Up until 1996–97 approximately 80% of the catch was taken in winter (June–July) when fish form aggregations for spawning. From 1997–98 onwards about 50% of the catch was taken in winter. Reported domestic landings and TACCs are shown in Table 1, while the historical landings and TACC for ORH 7B are depicted in Figure 1.

Table 1: Reported landings (t) of orange roughy and TACCs (t) for ORH 7B from 1983–84 to present. QMS data from 1986–present.

Fishing year	Reported landings	TACC
1983–84*	2	-
1984–85*	282	-
1985–86*	1 763	1 558
1986–87*	1 446	1 558
1987–88	1 413	1 558
1988–89	1 750	1 708
1989–90	1 711	1 708
1990–91	1 683	1 708
1991–92	1 604	1 708
1992–93	1 139	1 708
1993–94	701	1 708
1994–95	290	1 708
1995–96	446	430
1996–97	425	430
1997–98	330	430
1998–99	405	430
1999–00	284	430
2000–01	161	430
2001–02	95	110
2002–03	90	110
2003–04	119	110
2004–05	106	110
2005–06	77	110
2006–07	125	110
2007–08	6.0	1
2008–09	1.4	1
2009–10	< 0.1	1
2010–11	0.1	1
2011–12	< 0.1	1
2012–13	0.3	1

*FSU data.

Catches in the early-mid 1990s (especially 1994–95) were well below the TACC. The TACC was reduced to 430 t for the 1995–96 fishing year, then was reduced further to 110 t from 1 October 2001, followed by a further reduction to 1 t in the 2007–08 fishing year.

1.2 Recreational fisheries

There is no known recreational fishery for orange roughy in this area.

1.3 Customary non-commercial fisheries

There is no known customary non-commercial fishing for orange roughy in this area.

1.4 Illegal catch

There is no quantitative information available on illegal catch.

1.5 Other sources of mortality

There is no quantitative information available on other sources of mortality in this fishery.

ORANGE ROUGHY (ORH 7B)

Figure 1: Historical landings and TACC for ORH 7B (Auckland East). Note that this figure does not show data prior to entry into the QMS.

2. STOCKS AND AREAS

There is no new information which would alter the stock boundaries given in previous assessment documents.

Orange roughy in this fishery are thought to be a single stock. Genetic studies have shown that samples of Cook Canyon orange roughy are significantly different from Challenger Plateau and Puysegur Bank samples. Moreover, the size structure and parasite composition differ from fish on the Challenger Plateau. Spawning occurs at a similar time to fish on the Challenger Plateau and the Puysegur Bank.

3. STOCK ASSESSMENT

The previous assessment for this stock was carried out in 2004 and is summarised in the 2006 Plenary Report. Biomass was estimated to be 17% B_0 (95% confidence interval 14–23%) when CPUE was assumed to be directly proportional to abundance.

An updated assessment was attempted in 2007 with the addition of catch data up to 2005–06 and new standardised CPUE indices. The Working Group rejected the assessment on the basis of the poor fit to the CPUE data. The effect was similar to the result from the 2004 assessment; namely a slow rebuild in recent years, which was not supported by the CPUE data.

3.1 Estimates of fishery parameters and abundance

Commercial catch and effort data are available from 1985 and were examined using both an unstandardised and a standardised analysis. Unstandardised catch rates have declined substantially over the course of the fishery but have shown no clear trend in recent years (Table 2).

The standardised CPUE analysis has been divided into two series to address reporting form changes: (i) using TCEPR data from 1985–86 through to 1996–97, and (ii) using CELR data from 1990–91 through to 2005–06. In addition, in order to increase vessel linkage across years, it was decided to use all months of data not just that from the winter fishery (June–July) as has been done for previous standardisations.

Table 2: Summary of groomed data from TCEPR and CELR forms.

Fishing year	Number of vessel days	Number of tows	Total estimated catch (t)	Mean daily catch rate (t/tow)	Mean daily catch rate (t/h)
1985–86	138	357	1 544	4.5	2.9
1986–87	132	405	1 250	4.0	2.7
1987–88	132	420	1 250	3.4	2.3
1988–89	133	368	827	2.5	1.6
1989–90	123	356	1 282	4.5	5.6
1990–91	208	632	1 657	2.8	3.3
1991–92	238	810	1 601	2.0	1.4
1992–93	258	784	1 128	1.5	2.3
1993–94	298	708	660	1.1	0.9
1994–95	162	361	320	0.9	1.6
1995–96	66	150	275	2.2	1.7
1996–97	90	182	244	1.3	7.5
1997–98	96	228	170	0.7	0.3
1998–99	188	566	359	0.6	0.2
1999–00	213	647	259	0.4	0.1
2000–01	149	442	162	0.4	0.1
2001–02	117	282	76	0.3	0.1
2002–03	97	292	112	0.4	0.2
2003–04	90	252	118	0.4	0.2
2004–05	121	393	102	0.3	0.1
2005–06	87	257	73	0.3	0.2

The standardised analysis for the TCEPR data used catch per tow in a linear regression model. Indices from this model (Table 3, Figure 2) show a steep decline after the first two years, followed by a more gradual decline and a slight increase in catch rates in 1995–96 and 1996–97.

Table 3: Standardised CPUE indices (relative year effect) based on TCEPR data with number of vessel tows from 1985–86 to 1996–97.

Year	CPUE index	CV	Number of tows	Year	CPUE index	CV	Number of tows
1985–86	1.99	0.20	153	1991–92	0.48	0.23	231
1986–87	2.13	0.23	150	1992–93	0.29	0.23	230
1987–88	1.11	0.26	212	1993–94	0.14	0.25	341
1988–89	0.58	0.22	310	1994–95	0.13	0.27	172
1989–90	0.61	0.22	236	1995–96	0.51	0.33	37
1990–91	0.76	0.23	238	1996–97	0.41	0.26	104

The standardised analysis for the CELR data used daily catch in a linear regression model. Indices from this model (Table 4, Figure 2) show a steep decline for the first four years, followed by an increase to a peak in 1995–96, and subsequent low catch rates after then.

Table 4: Standardised CPUE indices (relative year effect) based on CELR data with number of days from 1990–91 to 2005–06.

Year	CPUE index	CV	Number of days	Year	CPUE index	CV	Number of days
1990–1991	2.17	0.27	110	1999–2000	0.34	0.27	131
1991–1992	1.11	0.27	108	2000–2001	0.34	0.28	88
1992–1993	0.74	0.27	126	2001–2002	0.33	0.28	73
1993–1994	0.28	0.28	81	2002–2003	0.61	0.26	67
1994–1995	0.53	0.30	46	2003–2004	0.59	0.25	75
1995–1996	1.16	0.33	29	2004–2005	0.35	0.24	114
1996–1997	0.53	0.38	19	2005–2006	0.36	0.26	80
1997–1998	0.36	0.30	52				
1998–1999	0.39	0.28	112				

Figure 2: The CPUE indices based on: (i) TCEPR data (solid line and crosses) covering 1985–86 to 1996–97, and (ii) CELR data (triangles and dashed line) covering 1990–91 to 2005–06. The CELR index has been scaled so that it has the same mean value as the TCEPR index in the years that they overlap.

3.2 Biomass estimates

No estimates of current biomass are available. Based on previous stock assessments using CPUE data the TACC was cut back severely from about 1700 t in 1994–95 to 110 t in 2000–01. By the late 1990s the stock was believed to be well below B_{MSY} where it continued until at least 2004 (17% B_0 in the 2004 assessment, Figure 3). Despite the large reduction in annual removals from the stock after 2001–02, catch rates did not increase over the subsequent 5 years.

An updated assessment was attempted in 2007 with the addition of catch data up to 2005–06 and new standardised CPUE indices (Figure 2) based on TCEPR data (1986 to 1997) and a separate CELR series (1991 to 2006). These data were incorporated in a Bayesian stock assessment with deterministic recruitment to estimate stock size. The Working Group rejected the assessment on the basis of the poor fit to the recent CPUE data. The model was insensitive to the recent CPUE data and predicted a rebuild (driven by the recruitment assumptions) that is not supported by any observations in the fishery.

Figure 3: Biomass trajectory derived from Maximum Posterior Density (MPD) estimate of the model parameters (2004 stock assessment). The biomass trajectory is shown by the solid line; crosses denote the CPUE index scaled to biomass.

4. STATUS OF THE STOCK

Stock Structure Assumptions

The ORH 7B stock has been treated as a single spawning stock located around the Cook Canyon area. It is assessed and managed separately from other stocks and is assumed to be non-mixing with orange roughy stocks outside of the Cook Canyon area.

Stock Status	
Year of Most Recent Assessment	2004
Assessment Runs Presented	One base case
Reference Points	Target: 30% B_0 Soft Limit: 20% B_0 Hard Limit: 10% B_0
Status in relation to Target	B_{2004} was estimated to be 17% B_0 , Very Unlikely (< 10%) to be at or above the target
Status in relation to Limits	B_{2004} was Likely (> 60%) to be below the Soft Limit and Unlikely (< 40%) to be below the Hard Limit

Historical Stock Status Trajectory and Current Status

Biomass trajectory derived from Maximum Posterior Density (2004 stock assessment model)

Fishery and Stock Trends	
Recent Trend in Biomass or Proxy	Unknown, but biomass is thought to be very low.
Recent Trend in Fishing Mortality or Proxy	The fishery has been effectively closed since October 2007.
Other Abundance Indices	-
Trends in Other Relevant Indicators or Variables	-

Projections and Prognosis (2004)	
Stock Projections or Prognosis	Stable at current catch level
Probability of Current Catch or TACC causing decline below Limits	Soft Limit: Already below the Soft Limit Hard Limit: Very Unlikely (< 10%)

ORANGE ROUGHY (ORH 7B)

Assessment Methodology	
Assessment Type	Type 1 - Quantitative stock assessment
Assessment Method	Age-structured model with Bayesian estimation of posteriors.
Main data inputs	- Catch history - CPUE indices (1985–2003)
Period of Assessment	Latest assessment: 2004 Next assessment: Unknown
Changes to Model Structure and Assumptions	- CPUE indices based on mean catch per hour as opposed to previous measure of mean catch per tow
Major Sources of Uncertainty	- Recruitment assumed to be deterministic - CPUE assumed to be directly proportional to stock biomass in base model

Qualifying Comments (2010)

A further assessment was attempted in 2007 with updated information; however, this was rejected by the working group as the model was insensitive to the CPUE data. The model indicated that the stock had been rebuilding since the mid 1990s, a trend not supported by any observations in the fishery. The fishery was closed from 1 October 2007 and stock size is expected to increase.

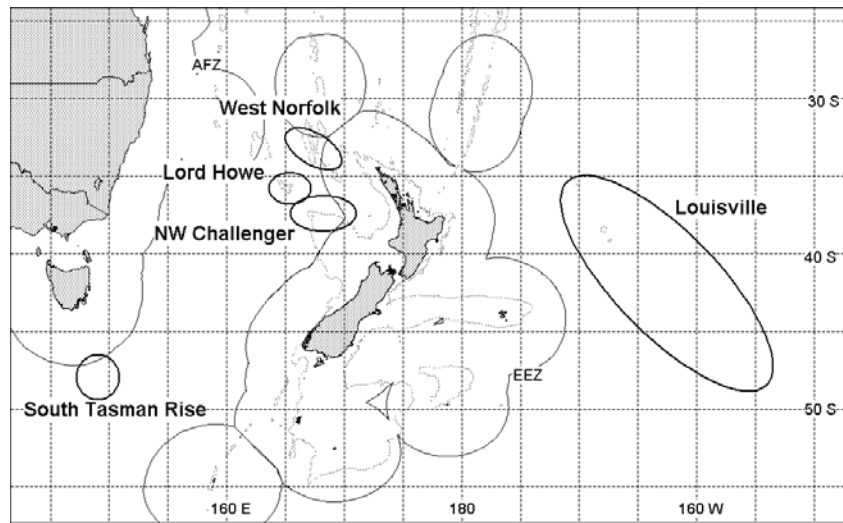

Fishery Interactions

Historically, the main bycatch species were oreos and deepwater dogfish. Bycatch species of concern included deepwater sharks, deepsea skates, seabirds and corals. The fishery is currently closed.

ORANGE ROUGHY OUTSIDE THE EEZ (ORH ET)

1. FISHERY SUMMARY

1.1 Commercial fisheries

Fisheries outside the EEZ in the New Zealand region occur on ridge systems and seamount chains in the Tasman Sea and southwest Pacific Ocean. There are five main fishing areas: Lord Howe Rise, Northwest Challenger Plateau, West Norfolk Ridge, South Tasman Rise, and Louisville Ridge (see figure above).

Fisheries outside the EEZ developed firstly on the “Westpac Bank” close to the main fishing grounds on the southwest Challenger Plateau in the early-mid 1980s. This is included in the stock area of ORH 7A, and so is not covered here. Further exploration in the region resulted in the development of commercial fisheries on the Lord Howe Rise in 1987–88, Northwest Challenger Plateau in 1988–89, Louisville Ridge in 1993–94, South Tasman Rise in 1997–98, and West Norfolk Ridge in 2001–02 (Table 1).

Table 1: Estimated catches (t) of orange roughy for ORH ET fisheries from 1987–88 to 2006–07. (Data from New Zealand (FSU, QMS), Australia (AFMA), and various sources for other countries. Note the fishing year for South Tasman Rise is March to February, all others are October to September).

Fishing year	Lord Howe	NW Challenger	Louisville	West Norfolk	South Tasman	Total ET
1987–88	4 000	5	0	0	0	4 005
1988–89	2 430	297	0	0	0	2 727
1989–90	927	425	0	0	0	1 352

Catch totals include data from New Zealand and Australian vessels available from tow by tow fishing records, with estimated catches added for vessels from Japan, USSR, Korea, Norway, South Africa and China. Catch statistics are likely to be incomplete.

ORANGE ROUGHY (ORH ET)

These fisheries have historically been unregulated, with the exception of the South Tasman Rise area, where catches by Australian and New Zealand vessels have at times been restricted by a TAC imposed under a Memorandum of Understanding between the two countries. The South Tasman Rise fishery is now formally closed.

South Pacific Regional Fisheries Management Organisation (SPRFMO) Convention Area

Regulation for these was implemented following adoption of the SPRFMO interim measures in May 2007, specific high sea fishing permits for the SPRFMO Area have been issued since 2007–08. Table 2 shows the number of vessels that fished and orange roughy catch by area. Since 2007, an orange roughy catch limit has been applied, being the average annual catch between 2002 and 2006, of 1852 t.

Table 2: Annual catch(t) and effort data for orange roughy from New Zealand vessels for the SPRFMO Area. Note that year is calendar year.

Year	Number of Vessels	Number of tows	Lord Howe	Challenger	Louisville	West Norfolk	Other	All areas
2007	8	415	34	36	280	515	0	866

2012	6	652	121	255	288	49	8	721

Lord Howe Rise

Commercial quantities of orange roughy were found by Japanese vessels in winter 1988, and New Zealand vessels joined the fishery the following year. A number of countries fished the Rise in the late 1980s, but since then it has been largely a New Zealand and Australian fishery. Tows were relatively long at the start of the fishery, when most fishing effort was on the flat ground of the broad platforms. However, shorter tows latterly became more common, associated with a shift onto rough ground and small hill features in the area. Levels of catch and effort decreased to low levels in the mid 1990s, but in recent years have tended to increase (Tables 2 & 3).

Table 3: Catch and effort data from New Zealand vessels for the Lord Howe Rise.

Fishing year	Number of tows	Total recorded catch (t)	Mean tow length (h)	Mean catch rate (t/tow)	Mean catch rate (t/h)	Mean catch rate (t/nmile)

2006–07	40	34	0.5	0.8	3.4	1.1

A reduced data set has been examined for 22 vessels that have fished for several years in the area until 2005–06 (Table 4). CPUE peaked in 1991–92, declined rapidly to low levels from 1994–95 to 1998–99, and increased over the last 5 years of the period.

Northwest Challenger Plateau

New Zealand and Norwegian vessels began working the northwestern margins of the Challenger Plateau in the late 1980s. Fishing initially was on relatively flat bottom but from 1990 onwards developed more on small hill and pinnacle features, and mean tow length became relatively short

(Table 5). Effort declined during the mid 1990s but increased substantially in 2000–01. Tow length increased also, as the fishery moved eastwards along the northern flanks of the Plateau in towards the EEZ. The hill fishery has decreased. Effort has also extended southwards along the western margins of the Challenger Plateau, although catches there have been small.

Table 4: Unstandardised CPUE indices for core vessels from Lord Howe Rise.

ORANGE ROUGHY (ORH ET)

Unstandardised CPUE for vessels that fished the area for several years through until 2005–06 has declined over time (Table 6). Average catch per tow was less than 1 t after 2000, even though the success of catching orange roughy (expressed as % of zero catch trawls) improved.

Catch rates in the hill fishery (winter, tow duration less than 30 minutes), decreased from a peak at around 4 t/tow in the mid 1990s to less than 1 t.

West Norfolk Ridge

This fishery developed from exploratory fishing inside the EEZ on the West Norfolk Ridge (ORH 1). In 2001–02 Australian vessels were involved as well as New Zealand vessels. Annual catches have typically been about 200–300 t (Table 7).

Table 7: Catch and effort data from New Zealand vessels for the West Norfolk Ridge orange roughy fishery.

Fishing year	Number of tows	Total recorded catch (t)	Mean tow length (h)	Mean catch rate (t/tow)	Mean catch rate (t/h)	Mean catch rate (t/nmile)
2000–01	1	0.2				
2001–02	297	586	0.3	2.0	9.0	3.0
2002–03	91	35	0.3	0.4	2.4	0.8
2003–04	90	88	0.5	1.0	2.3	0.8
2004–05	248	274	0.4	1.1	4.5	1.5
2005–06	337	727	0.4	2.2	19.7	6.6
2006–07	215	543	0.3	2.5	12.7	4.0

Fishing has been spread over the year, although highest catch rates have occurred in June and July, especially in 2005–06 and 2006–07.

Louisville Ridge

The Louisville Ridge is a chain of more than 60 seamounts extending for over 4000 km southeast from the Kermadec Ridge. Fishing began in 1993–94 in the central part of the ridge, and spread both northwest and southeast in subsequent years. The fishery has comprised largely New Zealand vessels, although vessels from Australia, China, Russia, Ukraine, Korea and Japan are known to have fished the ridge also (mainly in the first few years). The New Zealand catch peaked in 1994–95 at over 11 000 t but has subsequently reduced (Tables 2 & 8). Catch rates between 1993–94 and 2005–06 varied with a general decline in all areas (Table 9).

Table 8: Catch and effort data from New Zealand vessels for the Louisville Ridge.

Fishing year	Number of tows	Total recorded catch (t)	Mean tow length (h)	Mean catch rate (t/tow)	Mean catch rate (t/h)	Mean catch rate (t/nmile)
1993–94	134	189	1.4	1.4	1.5	0.6
1994–95	4 294	11 340	0.7	2.6	10.6	4.2

2006–07	283	323	0.5	1.1	8.5	2.6

Table 9: Average catch rate (tonnes per tow) of orange roughy in winter months (June to August) by New Zealand vessels from the Louisville Ridge, by sub-area from 1993–94 to 2005–06.

	Full Area	North	Central	South
1993–94	1.9	-	1.9	-
1994–95	2.7	3.9	2.6	11.0
1995–96	3.6	6.0	2.1	3.9
1996–97	2.1	1.4	2.0	3.5
1997–98	2.0	1.9	2.4	0.7
1998–99	2.7	2.1	2.9	1.7
1999–00	1.8	2.1	1.6	2.8
2000–01	2.3	2.6	2.0	1.9
2001–02	1.3	0.9	2.3	3.9
2002–03	1.9	1.7	1.2	5.3
2003–04	1.1	0.7	1.4	1.8
2004–05	2.1	1.8	1.6	2.9
2005–06	1.1	1.0	1.0	1.6

CPUE, from individual seamounts shows variable patterns. The fishery on some seamounts has lasted only a few years, while on others it has continued, or fluctuated over time. Seamounts in the northwestern and southeastern sections of the Ridge have not sustained consistent catches, and some localised depletion may have occurred.

South Tasman Rise

Exploratory fishing south of Tasmania located aggregations of orange roughy on the South Tasman Rise just outside the Australian Fishing Zone (AFZ) in late 1997. The fishery rapidly increased in the next four years (Table 10), with Australian and New Zealand vessels working several small hill features on the Rise. However, New Zealand vessels have not fished the South Tasman Rise since 2000–01. Effort dropped continuously from 2001–02, and mean catch per tow in 2004–05 was about 1 t/tow. Note that insufficient vessels have fished since 2005–06 to enable presentation of catch or effort summaries.

Table 10: Catch and effort data from the South Tasman Rise (combined Australian and New Zealand data).

Fishing year	Number of tows	Total recorded catch (t)	Mean tow length (h)	Mean catch rate (t/tow)	Mean catch rate (t/h)
1996–97	61	4	0.6	0.1	0.5
1997–98	1 132	3 930	0.7	3.5	17.4
1998–99	1 332	1 705	0.6	1.3	10.4
1999–00	1 086	3 360	0.5	3.1	21.1
2000–01	1 155	830	0.4	0.7	6.7
2001–02	201	170	0.8	1.0	3.5
2002–03	164	110	0.5	0.9	7.9
2003–04	67	2	0.3	0.1	0.4
2004–05	47	55	0.3	1.2	14.7

The fishery was formally regulated by a Memorandum of Understanding between Australia and New Zealand from December 1998. A precautionary TAC of 2100 t was applied, increased to 2400 t in 2000–01, and then progressively reduced to 600 t for 2004–05. The fishery was closed to all trawling in 2007.

1.2 Summary of trends in commercial fisheries

Since the high seas fishing permits for the SPRFMO Convention Area were implemented in 2007–08 the number of bottom trawl vessels actively fishing has varied from 4–8 vessels. Catch levels have decreased for all fisheries since they began, but after a period in the late 1990s–early 2000s when the total catch by New Zealand vessels was relatively consistent at 2000–2500 t. Trends in catch and effort have been difficult to interpret given changes in the vessel composition over time and the areas fished between years.

Mean catch rates for the Lord Howe Rise have been variable in recent years as the fishery has moved to hill features. The fishery appears to have become more consistent from year to year following a period of low catch and effort in the mid 1990s. The Louisville Ridge fishery has been the largest of those in the New Zealand region, but catch and effort levels have declined substantially since 2004–05. The patterns on individual seamounts differ, with some appearing stable, while others have

ORANGE ROUGHY (ORH ET)

declined. The West Norfolk Ridge fishery developed rapidly in 2001–02, and after an initial decrease in catch and effort, these increased in 2004–05 as new sites were fished. Catches increased substantially in 2005–06, and relatively large catches and high catch rates continued in 2006–07. The fishery on the South Tasman Rise decreased to very low levels during the early 2000s, and was closed in 2007. New Zealand vessels have not fished the Rise since 2001.

1.3 Recreational fisheries

There is no known non-commercial fishery for orange roughy in these areas.

1.4 Customary non-commercial fisheries

No customary non-commercial fishing for orange roughy is known in these areas.

1.5 Illegal catch

In most of these areas, there were no regulations regarding limits on catch in international waters prior to 2007. The South Tasman Rise region has been subject to catch restrictions for Australian and New Zealand vessels under a Memorandum of Understanding between the two countries. In 1999–2000 vessels registered in South Africa and Belize fished the region. The estimated catch of at least 750 t has been included in the catch total for that year. No other information is available on any possible illegal catch on the South Tasman Rise, or the Westpac Bank region of ORH 7A.

1.6 Other sources of mortality

There may be some overrun of reported catch because of fish loss with trawl gear damage, ripped nets, discards, and conversion factor inaccuracies. In a number of other orange roughy fisheries, a current level of 5% has been applied (higher in the past). No corrections are made here because of limited information on the sources which may differ with each fishery.

2. STOCKS AND AREAS

The five fishing grounds are all regarded as separate stocks.

The Lord Howe Rise and Northwest Challenger Plateau fisheries are based on fish that have a different size structure, different age/size at maturity, similar timing of spawning, and a geographical separation of about 120 n. miles. Their genetic make-up differs from fish on the southwest Challenger Plateau (ORH 7A). Morphometric differences have also been shown between orange roughy from Lord Howe and Puysegur Bank areas.

Orange roughy on the South Tasman Rise are regarded as a straddling stock with fish inside the AFZ.

The Louisville Ridge is a long seamount chain, and little is known about stock structure within the area. There are several known spawning sites, and it would seem likely that there could be multiple stocks or sub-populations along the ridge.

The fishery on the West Norfolk Ridge outside the EEZ is continuous with that carried out on ridge peaks and seamount features inside the EEZ.

3. STOCK ASSESSMENT

There are currently no accepted stock assessments for these orange roughy fisheries outside the EEZ. Several have been attempted (for Lord Howe, Northwest Challenger Plateau, and Louisville Ridge) based on catch per unit effort data, but these have not been accepted as sufficiently robust by the Deepwater Fishery Assessment Working Group. This was generally on account of highly variable levels of effort and catch between years within each of the fisheries, which can make the use of CPUE as an index of abundance uncertain.

4. STATUS OF THE STOCKS

The status of the stocks is unknown. Catch and effort levels have decreased substantially in some of the grounds in the last few years, and unstandardised CPUE has declined in a number of areas. However, it is not known if recent catch levels are sustainable, or whether they will allow the stocks to move towards a size that will support the *MSY*.

OREOS (OEO)

(*Allocyttus niger*, *Allocyttus verucosus*, *Neocyttus rhomboidalis* and *Pseudocyttus maculatus*)

1. INTRODUCTION

The main black oreo and smooth oreo fisheries have been assessed separately and individual reports produced for each as follows:

1. OEO 3A black oreo and smooth oreo
2. OEO 4 black oreo and smooth oreo
3. OEO 1 and OEO 6 black oreo and smooth oreo

2. BIOLOGY

2.1 Black oreo

Black oreo have been found within a 600 m to 1300 m depth range. The geographical distribution south of about 45° S is not well known. It is a southern species and is abundant on the south Chatham Rise, along the east coast of the South Island, the north and east slope of Pukaki Rise, the Bounty Platform, the Snares slope, Puysegur Bank and the northern end of the Macquarie Ridge. They most likely occur all around the slope of the Campbell Plateau.

Spawning occurs from late October to at least December and is widespread on the south Chatham Rise. Mean length at maturity for females, estimated from Chatham Rise trawl surveys (1986–87, 1990, 1991–93) using macroscopic gonad staging, is 34 cm TL.

They appear to have a pelagic juvenile phase, but little is known about this phase because only about 12 fish less than 21 cm TL have ever been caught. The pelagic phase may last for 4–5 years with lengths of up to 21–26 cm TL.

Unvalidated age estimates were obtained for Chatham Rise and Puysegur-Snares samples in 1995 and 1997 respectively using counts of the zones (assumed to be annual) observed in thin sections of otoliths. These estimates indicate that black oreo is slow growing and long lived. The maximum estimated age was 153 years (45.5 cm TL fish). Australian workers used the same methods, i.e., sections of otoliths,

and reported similar results. A von Bertalanffy growth curve was fitted to the Puysegur samples only (Table 1). Estimated age at maturity for females was 27 years.

A first estimate of natural mortality (M), 0.044 (yr^{-1}), was made in 1997 using the Puysegur growth data only. This estimate is uncertain because it appeared that the otolith samples were taken from a well fished part of the Puysegur area.

Black oreo appear to settle over a wide range of depths on the south Chatham Rise, but appear to prefer to live in the depth interval 600–800 m that is often dominated by individuals with a modal size of 28 cm TL.

2.2 Smooth oreo

Smooth oreo occur from 650 m to about 1500 m depth. The geographical distribution south of about 45° S is not well known. It is a southern species and is abundant on the south Chatham Rise, along the east coast of the South Island, the north and east slope of Pukaki Rise, the Bounty Platform, the Snares slope, Puysegur Bank and the northern end of the Macquarie Ridge. They most likely occur all around the slope of the Campbell Plateau.

Spawning occurs from late October to at least December and is widespread on the south Chatham Rise in small aggregations. Mean length at maturity for females, estimated from Chatham Rise trawl surveys (1986–87, 1990, 1991–93) using macroscopic gonad staging, is 40 cm TL.

They appear to have a pelagic juvenile phase, but little is known about this phase because only about six fish less than 16 cm TL have ever been caught. The pelagic phase may last for 5–6 years with lengths of up to 16–19 cm TL.

Unvalidated age estimates were obtained for Chatham Rise and Puysegur-Snares fish in 1995 and 1997 respectively using counts of the zones (assumed to be annual) observed in thin sections of otoliths. These estimates indicate that smooth oreo is slow growing and long lived. The maximum estimated age was 86 years (51.3 cm TL fish). Australian workers used the same methods, i.e., sections of otoliths, and reported similar results. A von Bertalanffy growth curve was fitted to the age estimates from Chatham Rise and Puysegur-Snares fish combined and the parameters estimated for the growth curve are in Table 1. Estimated age at maturity for females was 31 years.

An estimate of natural mortality, 0.063 (yr^{-1}), was made in 1997. The estimate was from a moderately exploited population of fish from the Puysegur region. The Puysegur fishery started in 1989–90 and by August–September 1992 (when the otoliths were sampled) about 24% of the smooth oreo catch from 1989–90 to 1995–96 had been taken. Future estimates of M should, if possible, be made from an unexploited population.

There are concentrations of recently settled smooth oreo south and south west of Chatham Island, although small individuals (16–19 cm TL) occur widely over the south Chatham Rise at depths of 650–800 m.

Table 1: Biological parameters used for black oreo and smooth oreo stock assessments. Values not estimated are indicated by (-). [Continued on next page].

Fishstock	Estimate		
<u>1. Natural Mortality - M (yr^{-1})</u>			
	Females	Males	Unsexed

Black oreo	-	-	-
Smooth oreo	21	21	
<u>3. Age at maturity A_M (yr)</u>			
Black oreo	27	-	-
Smooth oreo	31	-	

A New Zealand pilot study examined stock relationships using samples from four management areas (OEO 1, OEO 3A, OEO 4 and OEO 6) of the New Zealand EEZ. Techniques used included genetic (nuclear and mitochondrial DNA), lateral line scale counts, settlement zone counts, parasites, otolith microchemistry, and otolith shape. Otolith shape from OEO 1 and OEO 6 was different to that from OEO 3A and OEO 4 samples. Weak evidence from parasite data, one gene locus and otolith microchemistry suggested that northern OEO 3A samples were different from other areas. Lateral line scale and otolith settlement zone counts showed no differences between areas.

These data suggest that the stock boundaries given in previous assessment documents should be retained until more definitive evidence for stock relationships is obtained, i.e., retain the areas OEO 1, OEO 3A, OEO 4, and OEO 6 (see the figure on the first page of the Oreos assessment report above).

The four species of oreos (black oreo, smooth oreo, spiky oreo, and warty oreo) are managed with separate catch limits for black and smooth in some areas. Each species could be managed separately. They have different depth and geographical distributions, different stock sizes, rates of growth, and productivity.

4. FISHERY SUMMARY

4.1 Commercial fisheries

Commercial fisheries occur for black oreo (BOE) and smooth oreo (SSO). Oreos are managed as a species group, which also includes spiky oreo (SOR). The Chatham Rise (OEO 3A and OEO 4) is the main fishing area, but other fisheries occur off Southland on the east coast of the South Island (OEO 1/OEO 3A), and on the Pukaki Rise, Macquarie Ridge, and Bounty Plateau (OEO 6). In the past oreo catch has been taken as bycatch of the more valuable orange roughy fisheries but target fisheries are now much more common in most areas for smooth or black oreo.

Total reported landings of oreos and TACs are shown in Table 2, while Figure 1 depicts the historical landings and TACC values for the main OEO stocks. OEO 3A and OEO 4 were introduced into the QMS in 1982–83, while OEO 1 and OEO 6 were introduced later in 1986–87. Total oreo catch from OEO 4 exceeded the TAC from 1991–92 to 1994–95 and was close to the TAC from 1995–96 to 2000–01 (Table 2). Catch remained high in OEO 4 while the orange roughy fishery has declined. The OEO 4 TAC was reduced from 7000 to 5460 t in 2001–02 but was restored to 7000 t in 2003–04. The oreo catch from OEO 3A was less than the TAC from 1992–93 to 1995–96, substantially so in 1994–95 and 1995–96. The OEO 3A TAC was reduced from 10 106 to 6600 t in 1996–97. A voluntary agreement between the fishing industry and the Minister of Fisheries to limit catch of smooth oreo from OEO 3A to 1400 t of the total oreo TAC of 6600 t was implemented in 1998–99. Subsequently the total OEO 3A TAC was reduced to 5900 t in 1999–00, 4400 in 2000–01, 4095 in 2001–02 and 3100 t in 2002–03. Catch from the Sub-Antarctic area (OEO 6) increased substantially in 1994–95 and exceeded the TAC in 1995–96. The OEO 6 TAC was increased from 3000 to 6000 t in 1996–97. There was also a voluntary agreement not to fish for oreos in the Puysegur area which started in 1998–99. OEO 1 was fished under the adaptive management programme up to the end of 1997–98. The OEO 1 TAC reverted back to pre-adaptive management levels from 1998–99. Catches have declined since then, and from 1 October 2007 the TACC was reduced to 2500 t, and other sources of mortality were allocated 168 t.

Reported estimated catches by species from tow by tow data recorded in catch and effort logbooks (Deepwater, TCEPR, and CELR) and the ratio of estimated to landed catch reported are given in Table 3.

OREOS (OEO)

Table 2: Total reported landings (t) for all oreo species combined by Fishstock from 1978–79 to 2012–13 and TACs (t) from 1982–83 to 2012–13.

Descriptive analyses of the main New Zealand oreo fisheries were updated with data from 2006–07 in 2008. Standardised CPUE analyses of black and smooth oreo have been updated as follows:

- smooth oreo in OEO 3A in 2009;
- black oreo in OEO 4 in 2009;
- black oreo in OEO 6 (Pukaki) in 2009;
- smooth oreo OEO 6 (Bounty) in 2008;

OREOS (OEO)

Figure 1 [Continued]: Figure 1: Historical landings and TACC for the four main OEO stocks. From top to bottom: OEO 3A (South East Cook Strait/Kaikoura/Strathallan), OEO 4 (South East Chatham Rise), and OEO 6 (Sub-Antarctic). Note that these figures do not show data prior to entry into the QMS.

4.2 Recreational fisheries

There are no known recreational fisheries for black oreo and smooth oreo.

4.3 Customary non-commercial fisheries

There is no known customary non-commercial fishing for black oreo and smooth oreo.

4.4 Illegal catch

Estimates of illegal catch are not available.

4.5 Other sources of mortality

Dumping of unwanted or small fish and accidental loss of fish (lost codends, ripped codends, etc.) were features of oreo fisheries in the early years. These sources of mortality were probably substantial in those early years but are now thought to be relatively small. No estimate of mortality from these sources has been made because of the lack of hard data and because mortality now appears to be small. Estimates of discards of oreos were made for 1994–95 and 1995–96 from MFish observer data. This involved calculating the ratio of discarded oreo catch to retained oreo catch and then multiplying the annual total oreo catch from the New Zealand EEZ by this ratio. Estimates were 207 and 270 t for 1994–95 and 1995–96 respectively.

5. ENVIRONMENTAL AND ECOSYSTEM CONSIDERATIONS

This section was updated for the 2013 Fishery Assessment Plenary after review by the Aquatic Environment Working Group. An issue-by-issue analysis is available in the 2012 Aquatic Environment and Biodiversity Annual Review (www.mpi.govt.nz/Default.aspx?TabId=126&id=1644).

5.1 Role in the ecosystem

Smooth and black oreo dominate trawl survey relative abundance estimates of demersal fish species at 650–1200 m on the south and southwest slope of the Chatham Rise (e.g., Hart & McMillan 1998). They are probably also dominant at those depths on the southeast slope of the South Island and other southern New Zealand slope areas including Bounty Plateau, and Pukaki Rise. They are replaced at depths of about 700–1200 m on the east and northern slope of Chatham Rise by orange roughy. The south Chatham Rise oreo fisheries are relatively long-standing, dating from Soviet fishing in the 1970s but the effects of extracting approximately 6000 t per year of smooth oreo from the south Chatham Rise (OEO 4) ecosystem between 1983–84 and 2012–13 are unknown.

5.1.1 Trophic interactions

Smooth oreo feed mainly on salps (80%), molluscs (9%, of which 8% are squids but also including octopods), and teleosts (5%) (percentage frequency of occurrence in stomachs with food, Stevens et al 2011). Black oreo feed on teleosts (48%), crustaceans (36%), salps (24%), and cephalopods (mainly squid, 6%) (Stevens et al 2011). Diet varies with fish size but salps remained the main prey for smooth oreo in the largest fish with small numbers of Scyphozoa, fish and squids. Salps were the main prey for smaller black oreo but amphipods and natant decapod crustaceans were important for intermediate sized fish (Clark et al 1989). Smooth oreo and black oreo occur with orange roughy at times. Orange roughy diet was mainly crustaceans (58%), teleosts (41%), and molluscs (10%, particularly squids) (frequency of occurrence, Stevens et al 2011) suggesting little overlap with the salp-dominated diet of smooth oreo. Where they co-occur, orange roughy and black oreo may compete for teleost and crustacean prey.

Predators of oreos probably change with fish size. Larger smooth oreo, black oreo and orange roughy were observed with healed soft flesh wounds, typically in the dorso-posterior region. Wound shape and size suggest they may be caused by one of the deepwater dogfishes (Dunn et al 2010).

5.1.2 Ecosystem indicators

Tuck et al. (2009) used data from the Sub-Antarctic and Chatham Rise middle-depth trawl surveys to derive indicators of fish diversity, size, and trophic level. However, fishing for oreos occurs mostly deeper than the depth range of these surveys and is only a small component of fishing in the areas considered by Tuck et al. (2009).

5.2 Incidental catch (fish and invertebrates)

Anderson (2011) summarised the bycatch of oreo trawl fisheries from 1990–91 to 2008–09. Since 2002, oreo species (mainly smooth oreo and black oreo) accounted for about 92% of the total estimated catch from all observed trawls targeting oreos. Orange roughy (3.5%) was the main bycatch species, with no other species or group of species accounting for more than 0.6% of the total catch. Hoki were the next most common bycatch species, followed by rattails, deepwater dogfishes, especially Baxter's dogfish (*Etmopterus baxteri*) and seal shark (*Dalatias licha*), slickheads, and basketwork eel (*Diastobranchus capensis*), all of which were usually discarded. Ling were also frequently caught, but only comprised about 0.3% of the total catch. In total, over 250 species or species groups were identified by observers in the target fishery. Total annual fish bycatch in the oreo fishery since 1990–91 ranged from about 270 t to 2200 t and, apart from some higher levels in the late 1990s, did not show any obvious trends. Bycatch was split almost evenly between commercial and non-commercial species although, since 2002, about 60% of the bycatch was of commercial species.

The main invertebrate bycatch includes corals (almost 0.4% of the total catch, Anderson 2011), squids and octopuses, king crabs, and echinoderms. Tracey et al (2011) analysed the distribution of nine groups of protected corals based on bycatch records from observed trawl effort from 2007–08 to 2009–10, primarily from 800–1000 m depth. For the oreo target fishery, the highest catches were reported from the north and south slopes of the Chatham Rise, east of the Pukaki Rise, and on the Macquarie Ridge.

5.3 Incidental catch (seabirds, mammals, and protected fish)

For protected species, capture estimates presented here *include* all animals recovered to the deck of fishing vessels (alive, injured or dead), but do not include any cryptic mortality (e.g., a seabird struck by a warp but not brought on board the vessel, Middleton & Abraham 2007, Brothers et al 2010). Ramm (2011, 2012a, 2012b) summarised observer data for combined bottom trawl fisheries for orange roughy, oreos, cardinalfish and listed annual captures of seabirds, and mammals from 2008–09 to 2010–11.

5.3.1 Marine mammal interactions

There have been no observed incidental captures of New Zealand sea lions by trawlers targeting oreos from 2002–03 to date, but occasional captures of New Zealand fur seals are observed (which were classified as “Not Threatened” under the New Zealand Threat Classification System in 2010, Baker et al 2010). Between 2002–03 and 2012–13, there were 8 observed captures of New Zealand fur seals in oreo trawl fisheries, all prior to 2008–09. In the 2011–12 fishing year there were no observed captures (Table 4) but there were 2 (95% c.i. 0–10) estimated captures, with the estimates made using a statistical model (Thompson et al 2013). All observed fur seal captures occurred in the Sub-Antarctic region. The average rate of capture for the last ten years was less than 0.00 per 100 tows (range 0–0.38). This is a very low rate compared with that in the hoki fishery (1.28–5.63 per 100 tows).

Table 4: Number of tows by fishing year and observed and model-estimated total New Zealand fur seal captures in oreo trawl fisheries, 2002–03 to 2012–13. No. obs, number of observed tows; % obs, percentage of tows observed; Rate, number of captures per 100 observed tows, % inc, percentage of total effort included in the statistical model. Estimates are based on methods described in Thompson et al (2013) and available via <http://www.fish.govt.nz/en-nz/Environmental/Seabirds/>. Data for 2002–03 to 2011–12 are based on data version 20130304 and preliminary data for 2012–13 are based on data version 20140131.

	Observed					Estimated		
	Tows	No. obs	% obs	Captures	Rate	Captures	95% c.i.	% inc.
2002–03	2 834	302	10.7	0	0.00	3	0 – 14	100.0

5.3.2 Seabird interactions

Annual observed seabird capture rates ranged from 0.1 to 3.5 per 100 tows in the combined orange roughy, oreo, and cardinalfish trawl fisheries between 1998–99 and 2007–08 (Baird 2001, 2004 a,b,c, 2005, Abraham et al 2009, Abraham & Thompson 2011). However, in the oreo trawl fisheries only, capture rates have not been above 1 bird per 100 tows since 2005–06 and have fluctuated without obvious trend at this low level (Table 5). In the 2011–12 fishing year there was 1 observed bird capture in the oreo trawl fisheries, a rate of 0.23 birds per 100 observed tows with estimated captures of 8 (3-16) per 100 tows (Abraham et al 2013, Table 5). The average capture rate in the oreo trawl fisheries over the last ten years was only 0.34 birds per 100 tows, a low rate relative to trawl fisheries for squid (13.78), scampi (5.57) and hoki (2.16), birds per 100 tows over the same period.

Table 5: Number of tows by fishing year and observed seabird captures in orange roughy, oreo, and cardinalfish trawl fisheries, 2002–03 to 2012–13. No. obs, number of observed tows; % obs, percentage of tows observed; Rate, number of captures per 100 observed tows. Estimates are based on methods described in Abraham et al (2013) and available via <http://www.fish.govt.nz/en-nz/Environmental/Seabirds/>. Data for 2002–03 to 2011–12 are based on data version 20130304 and preliminary data for 2012–13 are based on data version 20140131.

OREOS (OEO)

Table 6: Number of observed seabird captures in oreo trawl fisheries, 2002–03 to 2012–13, by species and area. The risk ratio is an estimate of aggregate potential fatalities across trawl and longline fisheries relative to the Potential Biological Removals, PBR (from Richard & Abraham 2013 where full details of the risk assessment approach can be found). It is not an estimate of the risk posed by fishing for oreo. Other data, version 20130304.

Species	Risk Ratio	Chatham Rise	East Coast South Island	Subantarctic	Stewart-Snares Shelf	West Coast South Island	Total
Salvin's albatross	Very high	3	3	3	0	0	9
Chatham Island albatross	Very high	3	0	1	0	0	4
Total albatrosses	N/A	6	3	4	0	0	13
Cape petrel	High	0	1	0	0	0	1
White chinned petrel	Medium	0	1	0	0	0	1
Grey petrel	Medium	0	0	1	0	0	1
Sooty shearwater	Very low	0	3	0	1	0	4
NZ White-faced storm petrel	-	1	0	0	0	0	1
Total other birds	N/A	1	5	1	1	0	8

Salvin's albatross was the most frequently captured albatross (46% of observed albatross captures) but only two different species have been observed captured since 2002–03 (Table 6). Sooty shearwaters were the most frequently captured other taxon (50%, Table 6). Seabird captures in the oreo trawl fisheries were observed mostly off the east coast South Island. These numbers should be regarded as only a general guide on the distribution of captures because the observer coverage may not be representative.

Mitigation methods such as streamer (tori) lines, Brady bird bafflers, warp deflectors, and offal management are used in the orange roughy, oreo, and cardinalfish trawl fisheries. Warp mitigation was voluntarily introduced from about 2004 and made mandatory in April 2006 (Department of Internal Affairs 2006). The 2006 notice mandated that all trawlers over 28 m in length use a seabird scaring device while trawling (being “paired streamer lines”, “bird baffler” or “warp deflector” as defined in the Notice).

5.4 Benthic interactions

Orange roughy, oreos, and cardinalfish are taken using bottom trawls and accounted for about 14% of all tows reported on TCEPR forms to have been fished on or close to the bottom between 1989–90 and 2004–05 (Baird et al 2011). Black et al (2013) estimated that, between 2006–07 and 2010–11, 97% of oreo catch was reported on TCEPR forms. Tows are located in Benthic Optimised Marine Environment Classification (BOMECE, Leathwick et al 2009) classes J, K (mid-slope), M (mid-lower slope), N, and O (lower slope and deeper waters) (Baird & Wood 2012), and 94% were between 700 and 1 200 m depth (Baird et al 2011). Deepsea corals in the New Zealand region are abundant and diverse and, because of their fragility, are at risk from anthropogenic activities such as bottom trawling (Clark & O'Driscoll 2003, Clark & Rowden 2009, Williams et al 2010). All deepwater hard corals are protected under Schedule 7A of the Wildlife Act 1953. Baird et al (2012) mapped the likely coral distributions using predictive models, and concluded that the fisheries that pose the most risk to protected corals are these deepwater trawl fisheries.

Trawling for orange roughy, oreo, and cardinalfish, like trawling for other species, is likely to have effects on benthic community structure and function (e.g., Rice 2006) and there may be consequences for benthic productivity (e.g., Jennings 2001, Hermsen et al 2003, Hiddink et al 2006, Reiss et al 2009). These consequences are not considered in detail here but are discussed in the Aquatic Environment and Biodiversity Annual Review (Ministry for Primary Industries 2012).

The New Zealand EEZ contains 17 Benthic Protection Areas (BPAs) that are closed to bottom trawl fishing and include about 52% of all seamounts over 1500 m elevation and 88% of identified hydrothermal vents.

5.5 Other considerations

5.5.1 Spawning disruption

Fishing during spawning may disrupt spawning activity or success. Morgan et al (1999) concluded that Atlantic cod (*Gadus morhua*) “exposed to a chronic stressor are able to spawn successfully, but there appears to be a negative impact of this stress on their reproductive output, particularly through the production of abnormal larvae”. Morgan et al (1997) also reported that “Following passage of the trawl, a 300-m-wide “hole” in the [cod spawning] aggregation spanned the trawl track. Disturbance was detected for 77 min after passage of the trawl.” There is no research on the disruption of spawning smooth oreo and black oreo by fishing in New Zealand, but spawning of both species appears to be over a protracted period (October to February) and over a wide area (O’Driscoll et al 2003). Fishing continues during the spawning period, possibly because localised spawning schools of smooth oreo, in particular, may provide good catch rates.

5.5.2 Genetic effects

Fishing, environmental changes, including those caused by climate change or pollution, could alter the genetic composition or diversity of a species. There are no known studies of the genetic diversity of smooth or black oreo from New Zealand. Genetic studies for stock discrimination are reported under “stocks and areas”.

5.5.3 Habitat of particular significance to fisheries management

Habitat of particular significance for fisheries management does not have a policy definition currently although work is currently underway to generate one. O’Driscoll et al. (2003) identified the south Chatham Rise as important for smooth oreo spawning, and the north, east and south slope as important for juveniles. The south Chatham Rise is also important for black oreo spawning and juveniles. Deepsea corals such as the reef-forming scleractinian corals and gorgonian sea fan corals are thought to provide prey and refuge for deep-sea fish (Fosså et al 2002, Stone 2006, Mortensen et al 2008). Large aggregations of deepwater species like orange roughy, oreos, and cardinalfish occur above seamounts with high densities of such “reef-like” taxa, but it is not known if there are any direct linkages between the fish and corals. Bottom trawling for orange roughy, oreos, and cardinalfish has the potential to affect features of the habitat that could qualify as habitat of particular significance to fisheries management.

OREOS — OEO 3A BLACK OREO AND SMOOTH OREO

1. FISHERY SUMMARY

This is presented in the Fishery Summary section at the beginning of the Oreos report.

2. BIOLOGY

This is presented in the Biology section at the beginning of the Oreos report.

3. STOCKS AND AREAS

This is presented in the Stocks and Areas section at the beginning of the Oreos report.

4. STOCK ASSESSMENT

The smooth oreo stock assessment is unchanged from 2009. The black oreo stock assessment for 2008 has been withdrawn but the CPUE series has been updated to 2012.

4.1 Introduction

The following assumptions were made in the stock assessment analyses to estimate biomasses and yields for black oreo and smooth oreo.

- (a) The acoustic abundance estimates were unbiased absolute values.
- (b) The CPUE analyses provided indices of abundance for either black oreo or smooth oreo in the whole of OEO 3A. Most of the oreo commercial catches came from the CPUE study areas. Research trawl surveys indicated that there was little habitat for, and biomass of, black oreo or smooth oreo outside those areas.
- (c) The ranges used for the biological values covered their true values.
- (d) The maximum fishing mortality (F_{MAX}) was assumed to be 0.9, varying this value from 0.5 to 3.5 altered B_0 for smooth oreo in OEO 3A by only about 6% in the 1996 assessment.
- (e) Recruitment was deterministic and followed a Beverton and Holt relationship with steepness of 0.75.
- (f) Catch overruns were 0% during the period of reported catch.
- (g) The populations of black oreo and smooth oreo in OEO 3A were discrete stocks or production units.
- (h) The catch histories were accurate.

4.1.1 Black oreo

The last accepted assessment was in 2008. A three-area population model was used to accommodate the structure of the catch and length data, with age-dependent migration between areas. However, new age data collected within each area suggest that, based on 2013 analyses, assumptions made by this model are incorrect. Specifically, differences in the size distribution between areas now seem likely to be due to differential growth rates, rather than to movement. The model applied in 2008 was therefore considered inadequate and has been withdrawn. No stock assessment is presented here; a new approach needs to be developed.

4.1.2 Smooth oreo

A new assessment of smooth oreo in OEO 3A was completed in 2009. This used a CASAL age-structured population model employing Bayesian methods. Input data included research and observer-collected length data, one absolute abundance estimate from a research acoustic survey carried out in 1997 (TAN9713), and three relative abundance indices from standardised catch per unit effort analyses.

4.2 Black oreo

Partition of the main fishery into 3 areas

The main fishery area was split into three areas: a northern area that contained small fish and was generally shallow (Area 1), a southern area that contained large fish in the period before 1993 and which was generally deeper (Area 3), and a transition area (Area 2) that lay between Areas 1 and 3 (Figure 1).

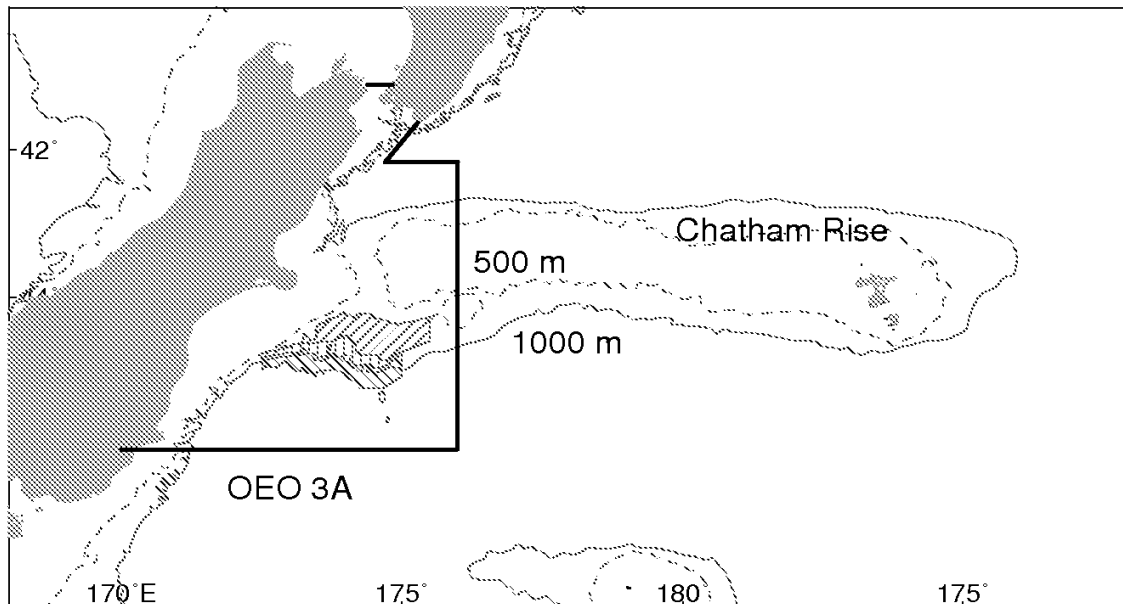

Figure 1: The three spatial areas used in the CASAL model and 2002 acoustic abundance survey. Area 1 at the top with right sloping shading; Area 2 in the middle with vertical shading; Area 3 at the bottom with left sloping shading. The thick dark line encloses management area OEO 3A.

The boundary between Areas 1 and 2 was defined in terms of the northern edge of the area that enclosed 90% of the total catch from the fishery. Areas 2 and 3 contained most of the fishery while Area 1 consisted of lightly fished and unfished ground. The boundary between Areas 2 and 3 was defined by the 32.5 cm contour in mean fish length for data before 1993 so that the fishery is split into an area containing smaller fish and another that has larger fish. The population outside the main fishery was assumed to follow the same relative dynamics.

Rejection of spatial model based on migration

The previous model reconciled the differences in commercial length distribution by using three areas. No age data were incorporated and instead lengths were used as a proxy for age. The dynamics were assumed to be recruitment in the shallow area (Area 1), with migration from Area 1 to Area 2, and also from Area 2 to Area 3, i.e., a one way movement to generally deeper water. The differences in the length distributions between areas drove the estimated migration rates by age. The stock assessment predicted that mature fish in the relatively unfished area (Area 1) comprised about 25% B_0 and so there were no sustainability concerns as this area was largely not fished.

To test the above migration hypothesis, otoliths sampled from acoustic survey mark identification trawls were aged and age distributions estimated for Area 1 and for the combined Areas 2 and 3 (Doonan, pers. comm.). The results showed deficiencies in the use of length data as a proxy for age in the stock assessment model. The age frequency in Area 1 was similar to that from Areas 2 and 3, but the model predicted them to be very different. Growth in Areas 2 and 3 appears to be faster than in Area 1 and this may drive the observed differences in length distributions. The migration model assumed the same growth in all areas. Maturity may be related to length rather than age, but it is age-based in the model. For these reasons, the Working Group rejected the stock assessment model in 2013. No formal stock assessment is presented here.

4.2.1 Estimates of fishery parameters and abundance

Catches by area

Catches were partitioned into the three areas by scaling up the estimated catch of black oreo from each area to the total reported catch (see tables 2 and 3 in the Fishery Summary section at the beginning of the Oreos report) and are given in Table 1.

Table 1: Estimated black oreo catch (tonnes) for each fishing year in the three spatial model areas.

Year	Area 1	Area 2	Area 3	Total

† Soviet catch, assumed to be mostly from OEO 3A and to be 50:50 black oreo: smooth oreo.

Observer length frequencies by area

Catch at length data collected by observers in Areas 1, 2, and 3 were extracted from the *obs_lfs* database (Table 2). Derived length frequencies for each group were calculated from the sample length frequencies weighted by the catch weight of each sample.

Table 2: Number of observed commercial tows where black oreo was measured for length frequency. A total of 60 tows were excluded because they had fewer than 30 fish measured, extreme mean lengths or missing catch information.

Year	Area 1	Area 2	Area 3	Other

Research acoustic survey length frequencies by area

The 1997, 2002, 2006 and 2011 acoustic survey abundance at length data were converted to a length frequency using the combined sexes fixed length-weight relationship (“unsexed” in table 1, Biology section above) to convert the abundance to numbers at length (Table 3).

Absolute abundance estimates from the 1997, 2002, 2006 and 2011 acoustic surveys

Absolute estimates of abundance for black oreo are available from four acoustic surveys of oreos carried out from 10 November to 19 December 1997 (TAN9713), 25 September to 7 October 2002 (TAN0213), 17–30 October 2006 (TAN0615) and 17 November to 1 December 2011 (SWA1102). The 1997 survey covered the “flat” with a series of random north-south transects over six strata at depths of 600–1200 m. Seamounts were also sampled using parallel and “starburst” transects. Targeted and some random (background) trawling was carried out to identify targets and to determine species composition. The 2002 survey was limited to flat ground with 77 acoustic transect and 21 mark identification tows completed. The 2006 (78 transects and 22 tows) and 2011 (72 transects and 25 tows) surveys were very similar to the 2002 survey and covered the main area of the black oreo fishery. The estimated total abundance (immature plus mature) for each survey by area is shown in Table 4.

Table 3: Research length frequency proportions for the model area for the 1997, 2002, 2006 and 2011 acoustic surveys. - no data. For 1997 to 2006, lengths below 25 cm and greater than 38 were pooled.

Table 4: Total (immature plus mature) black oreo abundance estimates (t) and CVs for the 1997, 2002, 2006 and 2011 acoustic surveys for the three model areas in OEO 3A.

Acoustic survey	Area 1	Area 2	Area 3	Total
1997	148 000 (29)	10 000 (26)	5 240 (25)	163 000 (26)
2002	43 300 (31)	15 400 (27)	4 710 (38)	64 000 (22)
2006	56 400 (37)	16 400 (30)	5 880 (34)	78 700 (30)
2011	138 100 (27)	36 800 (30)	7 400 (34)	182 300 (25)

Relative abundance estimates from standardised CPUE analysis

Standardised CPUE indices were obtained for each area. Because of the apparent changes in fishing practice attributable to the introduction of GPS, the data were split into pre- and post-GPS series. There were also major changes in the fishery from 1998–99 to 2001–02 when there were TACC reductions and the start of a voluntary industry catch limit on smooth oreo (1998–99). Two post-GPS series were therefore developed. The first of these was from 1992–93 to 1997–98 (early series) and the second was from 2002–03 onwards (late series) with data from the intervening years ignored. Since there are no new data for either the pre-GPS series or the post-GPS early series, these are left unchanged from previous standardisation results. Only the post-GPS late series is updated here, using data that now extends from 2002–03 to 2011–12.

Only data within a pre-defined spatial area were considered useful for assessing abundance (Figure 2).

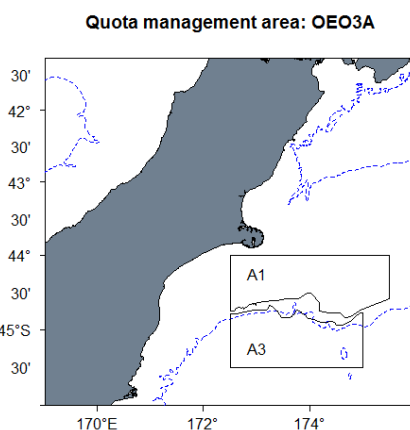

Figure 2: Spatial areas from which CPUE data were collected for inclusion in the standardisation. Areas A1 and A3 are shown, with A2 being the area between the two.

This area corresponds to the main fishing area and overlaps with the acoustic survey area (Figure 1). Tows were initially selected for inclusion in the CPUE standardisation if they targeted or caught black oreo within this area.

Uncertainty was assessed by bootstrapping the data, re-estimating the indices for each iteration, and estimating the coefficient of variation (CV) for each year/area from this distribution. The indices and CV estimates are listed in Table 5 and shown in Figure 3.

Table 5: OEO 3A black oreo pre-GPS and post-GPS time series of standardised catch per unit effort indices and bootstrapped CV estimates (%). Values for each series have been renormalized to a geometric mean of one. -, no estimate.

Figure 3: Standardised commercial CPUE series for black oreo in each area within OEO 3A. Pre-GPS and post-GPS (early and late) series are shown, each renormalized to a geometric mean of one. Error bars represent the 95% confidence intervals assuming a log-normal error distribution and using the CVs listed in Table 5.

4.3 Smooth oreo

2009 assessment

The stock assessment analyses were conducted using the CASAL age-structured population model employing Bayesian statistical techniques. The 2005 assessment was updated by including five more years of catch, CPUE and observer length data, and used two new series of post-GPS standardised CPUE, one before and the second after major TACC and catch limit changes. The modelling took account of the sex and maturity status of the fish and treated OEO 3A as a single smooth oreo fishery, i.e., no sub-areas were recognised. The base case model used the 1997 absolute acoustic abundance estimate, pre-GPS and early and late post-GPS series of standardised CPUE indices, and the mean natural mortality estimate (0.063 yr^{-1}). Acoustic and observer length frequencies were used in a preliminary model run to estimate selectivity and the base case fixed these selectivity estimates but did not use the length frequencies. Other cases investigated the sensitivity of the model to data sources including:

- Use of the upper and lower 95% confidence interval values for estimates of natural mortality ($0.042\text{--}0.099 \text{ yr}^{-1}$);
- Use of only the left hand limb of the 1994 observer length frequency (plus the 1997 acoustic survey length frequency) with growth not estimated by the model.

4.3.1 Estimates of fishery parameters and abundance

Catch history

The estimated catches were scaled up to the total reported catch (see tables 2 and 3 in the Fishery Summary section at the beginning of the Oreos report) and are given in Table 6.

Table 6: Reconstructed catch history (t)

Year	Catch	Year	Catch	Year	Catch	Year	Catch

† Soviet catch, assumed to be mostly from OEO 3A and to be 50 : 50 black oreo : smooth oreo.

Observer length frequencies

Observer length data were extracted from the observer database. These data represent proportional catch at length and sex. All length samples were from the CPUE study area (see Figure 4). Only samples where 30 or more fish were measured, and the catch weight and a valid depth were recorded, were included in the analysis. Data from adjacent years were pooled because of the paucity of data in some years. The pooled length frequencies were applied in the model at the year that the median observation of the grouped samples was taken (Table 7).

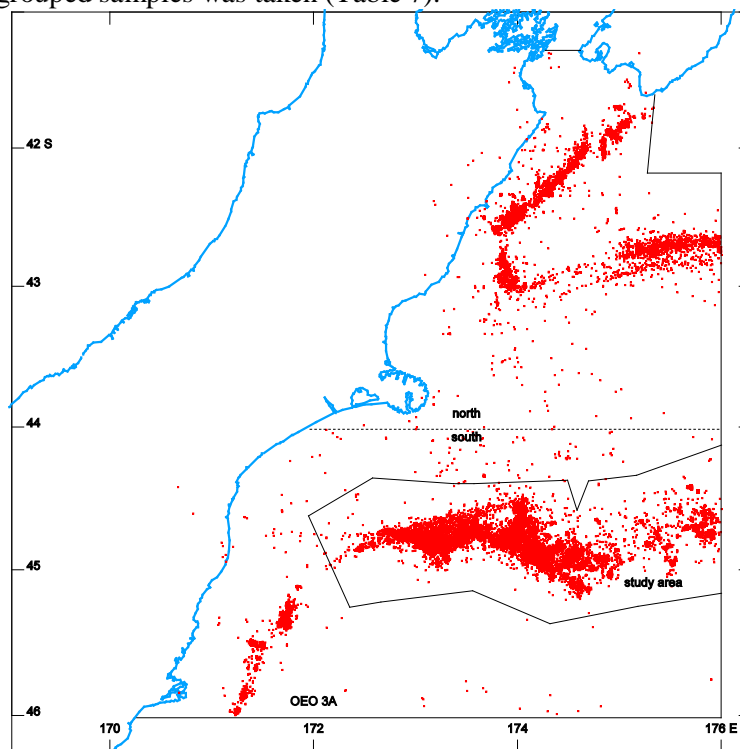

Figure 4: Locations of all tows in OEO 3A with a reported catch of smooth oreo from 1979-80 to 2002-03 (dots). The study area is shown along with the line chosen to split north from south Chatham rise catches.

Length frequency data from the 1997 acoustic survey

Length data collected during the 1997 survey were used to generate a population length frequency by sex. A length frequency was generated from the trawls in each mark-type and also for the seamounts. These frequencies were combined using the fraction of smooth oreo abundance in each mark-type. The overall frequency was normalised over both male and female frequencies so that the sum of the frequencies over both sexes was 100%. The CV for each length class was given by the regression, $\log(CV) = 0.86 + 8.75/\log(\text{proportion})$. This regression was estimated from the CVs obtained by bootstrapping the data and provides a smoothed estimate of the CVs. The estimated length frequency is in Figure 5.

Absolute abundance estimates from the 1997 acoustic survey

Absolute estimates of abundance for smooth oreo are available from the acoustic survey on oreos carried out from 10 November to 19 December 1997 (TAN9713) using the same approach as described for OEO 3A black oreo. The abundance estimates used in the 1999 OEO 3A smooth oreo assessment were revised in 2005 using new target strength estimates for smooth oreo, black oreo and a number of bycatch species. The revised estimate was 25 200 t with a CV of 23% (the 1999 estimate was 35 100 t with a CV of 27%). There is uncertainty in the estimates of biomass because the acoustic estimate includes smooth oreo in layers that are a mixture of species for which the acoustic method has potential bias problems.

Figure 5: Population length frequency derived from the 1997 acoustic survey data. The bold line is the estimated value and the shaded area is the spread from 300 bootstraps.

Relative abundance estimates from standardised CPUE analysis

The CPUE study area is shown in Figure 5. Three analyses were carried out; a pre-GPS analysis (unchanged from 2005) that included data from 1980–81 to 1988–89 and two post-GPS analyses that included data from 1992–93 to 1997–98 and 2002–03 to 2007–08. The years from 1998–99 to 2001–02 were not included because a voluntary smooth oreo of catch limit (1400 t) was introduced and substantial oreo TACC reductions were made during that time (6600 down to 3100 t). The pre-GPS series shows a downward trend down, and declines to approximately a third of the initial level over the nine-year period. The early post-GPS also has a downward trend but the late post-GPS series has an upward trend and then flattens out. The base case stock assessment used all three indices (Table 8).

Fishing Industry members of the Deepwater Fishery Assessment Working Group expressed concern about the accuracy of the historical Soviet catch and effort data (pre-GPS series) and felt that it was inappropriate to use those data in the stock assessment.

Table 8: CPUE indices by year and jackknife CV (%) estimates from the pre-GPS and the two post-GPS analyses.

Year	Pre-GPS			Post-GPS				
	Index	CV	Year	Index	CV	Year	Index	CV
1980–81	1.00	27	1992–93	1.00	24	2002–03	0.55	23
1981–82	0.82	26	1993–94	0.88	11	2003–04	0.77	22
1982–83	0.72	62	1994–95	0.74	14	2004–05	0.99	22
1983–84	0.59	61	1995–96	0.48	17	2005–06	0.96	31
1984–85	0.72	22	1996–97	0.56	15	2006–07	1.00	20
1985–86	0.61	19	1997–98	0.50	19	2007–08	0.92	21
1986–87	0.46	16						
1987–88	0.42	16						
1988–89	0.26	28						

4.3.2 Biomass estimates

The posterior distributions from the MCMC on the base case are shown in Figure 6. The probability that the current mature biomass (2008–09) and the biomass 5 years out (2013–14) are above 20% B_0 is 1 for both.

Biomass estimates derived from the MCMC are in Table 9. Total mature biomass for 2008–09 was estimated to be 36% of the initial biomass (B_0). Sensitivity case results for the base case using the lower and upper 95% confidence interval value estimates for M gave estimates of current biomass between 26% and 49% of B_0 . The sensitivity case that used the left hand limb of the 1994 observer length frequency (plus the 1997 acoustic survey length frequency) with growth not estimated by the model gave estimates of current biomass for the mean estimate of M (0.063 yr^{-1}) of 30% of B_0 while estimates using the lower and upper 95% confidence interval value estimates for M gave estimates of 2008 biomass between 12% and 59% of B_0 .

Projections were carried out for five years with the current catch limit of 1400 t. The trajectory shows increasing biomass (Figure 6).

4.3.3 Other factors

Because of differences in biological parameters between the species, it would be appropriate to split the current TACC for black oreo and smooth oreo. The WG noted that separate species catch limits are in place to reduce the risk of over- or under-fishing either smooth oreo or black oreo.

The model estimates of uncertainty are unrealistically low. Uncertainties that are not included in the model include:

- the assumption that recruitment is deterministic;
- that the acoustic index is assumed to be an absolute estimate of abundance;
- the selectivity in the base case is fixed at the MPD estimate from the preliminary case where all length data is used;
- uncertainty in the estimate of M .

In addition, the growth is fixed and known. The WG has previously noted the impact of the different ages of maturity for males and females. Due to the fact that males mature at a much smaller size than

females (age at 50% maturity is 18–19 years for males and 25–26 for females), the sex ratio needs to be taken into account when assessing the sustainability of any particular catch level.

Figure 6: Smooth oreo OEO 3A: posterior distribution for the virgin biomass (top plot) and the mature biomass trajectories as a percentage of virgin biomass (bottom plot) from the MCMC analysis of the “NoLF” case with $M = 0.063$ (base case). In the top plot, the vertical line is the median of the distribution. In the bottom plot, the grey area is the point-wise 95% confidence intervals of the trajectories and the solid line is the median.

Table 9 (a): Base case (in bold) and sensitivity to M values (biomass estimates). Bcurr is 2008.

	$M = 0.063$			$\dagger M = 0.042$			$\dagger M = 0.099$		
	Median	CI.05	CI.95	Median	CI.05	CI.95	Median	CI.05	CI.95
B_0	85 000	77 300	96 500	97 700	90 100	110 000	68 500	60 300	79 600
B_{cur}	30 900	22 400	43 000	26 300	18 000	38 800	33 800	25 000	45 500
$B_{cur}(\%B_0)$	36	29	45	27	20	35	49	41	57

(b) Sensitivity (biomass estimates). In these runs the left hand limb of the 1994 observer length was fitted, the 1997 acoustic survey length frequency was included and growth was not estimated by the model:

	$\dagger M = 0.063$			$\dagger M = 0.042$			$\dagger M = 0.099$		
	Median	CI.05	CI.95	Median	CI.05	CI.95	Median	CI.05	CI.95
B_0	77 400	74 800	80 200	82 800	81 600	84 200	82 300	76 700	89 200

$B_{cur}(\%B_0)$	30	27	33	12	10	14	59	56	63

5. STATUS OF THE STOCKS

The smooth oreo stock assessment is unchanged from 2009. The stock status of black oreo assessment is updated using CPUE data up to 2011–12.

Stock Structure Assumptions

The two oreo stocks in FMA 3A are assessed separately but managed as a single stock. For both the black oreo and smooth oreo stocks it is assumed that there is potential mixing with stocks outside of the OEO 3A area.

- **OEO 3A (Black Oreo)**

Stock Status	
Year of Most Recent Assessment	2013
Assessment Runs Presented	Age-structured CASAL spatial assessment model rejected by the Working Group; CPUE accepted
Reference Points	Target: 40% B_0 Soft Limit: 20% B_0 Hard Limit: 10% B_0 Overfishing threshold: $F_{40\% B_0}$

Qualifying Comments	
-	

Fishery Interactions

Both species of oreo are sometimes taken as bycatch in orange roughy target fisheries, mostly in other areas e.g. OEO 4. The main bycatch species in the OEO 3A black oreo target fishery include smooth oreo, hoki, javelinfish, Baxter’s dogfish, pale ghost shark, ridge scaled rattail, and basketwork eel. Bycatch species that may be vulnerable to overfishing include deepwater sharks and rays. Protected species catches include seabirds and deepwater corals.

- **OEO 3A (Smooth Oreos)**

Stock Status

Year of Most Recent Assessment	2009
Assessment Runs Presented	One base case and 5 sensitivity runs
Reference Points	Target: 40% B_0 Soft Limit: 20% B_0 Hard Limit: 10% B_0
Status in relation to Target	For the base case, B_{2009} was estimated at 36% B_0 , About as Likely as Not (40–60%) to be at or above the target.
Status in relation to Limits	B_{2009} is Unlikely (< 40%) to be below the Soft Limit and Very Unlikely (< 10%) to be below the Hard Limit.

Historical Stock Status Trajectory and Current Status

Mature biomass trajectories as a percentage of virgin biomass from the base case. The grey area is the point-wise 95% confidence intervals of the trajectories and the solid line is the median.

Fishery and Stock Trends

Recent Trend in Biomass or Proxy	Biomass is projected to have been increasing since the late 1990s.
Recent Trend in Fishing Mortality or Proxy	Unknown
Other Abundance Indices	-
Trends in Other Relevant Indicators or Variables	-

Projections and Prognosis (2009)

Stock Projections or Prognosis	The biomass is expected to increase over the next 5 years given the current catch limit of 1400 t.
Probability of Current Catch or TACC causing decline below Limits	Soft Limit: Very Unlikely (< 10%) Hard Limit: Very Unlikely (< 10%)

Assessment Methodology	
Assessment Type	Level 1 - Quantitative stock assessment
Assessment Method	Age-structured CASAL model with Bayesian estimation of posterior distributions
Main data inputs	<ul style="list-style-type: none"> - One acoustic absolute abundance estimate (1997) - three standardised CPUE indices (1981–82 to 1988–89, 1992–93 to 1997–98, 2002–03 to 2007–08) - Natural mortality estimate (0.063) - Selectivity estimated from acoustic and observer length frequencies New information from previous (2005) assessment: <ul style="list-style-type: none"> - Updated with additional catch, CPUE, observer length data collected since last assessment - two new standardised post-GPS CPUE series
Period of Assessment	Latest assessment: 2009 Next assessment: Unknown
Changes to Model Structure and Assumptions	-
Major Sources of Uncertainty	<ul style="list-style-type: none"> - The single acoustic index (1997) is assumed to be an absolute estimate of abundance - Sex ratio needs to be taken into account, as males mature at a much smaller size than females. - Recruitment is assumed to be deterministic. - Uncertainty in the estimates of natural mortality (M) - Selectivity is fixed in the base case at the MPD estimate from the preliminary study

Qualifying Comments

OREOS – OEO 4 BLACK OREO AND SMOOTH OREO

1. FISHERY SUMMARY

This is presented in the Fishery Summary section at the beginning of the Oreos report.

2. BIOLOGY

This is presented in the Biology section at the beginning of the Oreos report.

3. STOCKS AND AREAS

This is presented in the Stocks and Areas section at the beginning of the Oreos report.

4. STOCK ASSESMENT

4.1 Introduction

In 2012, a new stock assessment for smooth oreos in OEO 4 was presented.

4.2 Black oreo

Investigations were carried out in 2009 using age-based single sex single step preliminary models in CASAL. The data used in these models were four standardised CPUE indices (pre and post GPS in the east and west), and observer length frequencies. Growth and maturity were also estimated in some of the runs.

4.2.1 Estimates of fishery parameters and abundance

Absolute abundance estimates from the 1998 acoustic survey

Absolute estimates of abundance were available from an acoustic survey on oreos which was carried out from 26 September to 30 October 1998 on *Tangaroa* (voyage TAN9812). Transects on flat ground were surveyed to a stratified random design and a random sample of seamounts were surveyed with either a random transect (large seamounts) or a systematic “star” transect design. For some seamounts the flat ground nearby was also surveyed to compare the abundance of fish on and near the seamount either by extending the length of the star transects or by extra parallel transects. Acoustic data were collected concurrently for flat and seamounts using both towed and hull mounted transducers. The OEO 4 survey covered 59 transects on the flat and 29 on seamounts. A total of 95 tows were carried out for target identification and to estimate target strength and species composition. *In situ* and swimbladder samples for target strength data were collected and these have yielded revised estimates of target strength for both black oreo and smooth oreo.

Acoustic abundance estimates for recruit black oreo from seamounts and flat for the whole of OEO 4 are in Table 1. About 59% of the black oreo abundance came from the background mark-type. This mark-type is not normally fished by the commercial fleet and this implies that the abundance estimate did not cover the fish normally taken by the fishery. In addition the scaling factor to convert the acoustic area estimate to the trawl survey area estimate was 4.3, i.e., the acoustic survey area only had about 23% of the abundance. The magnitude of this ratio suggests that the size of the area surveyed was borderline for providing a reliable abundance estimate.

Relative abundance estimates from standardised CPUE analyses – 2009 analysis

The CPUE analysis involved applying regression based methods to the positive catches only. Sensitivities were run in which the zero catch and the positive catch tow data were analysed separately to produce zero catch and positive catch indices. All data were included, whether they were from target or bycatch fisheries, with the target species offered to the model as a variable (but not accepted).

OREOS (OEO 4)

Table 1: OEO 4 recruit black oreo seamount, flat, and total acoustic abundance estimates (t) and recruit CV (%) based on knife-edge recruitment (23 years).

	Abundance (t)	CV (%)
Seamount	127	91
Flat	13 800	56
Total	13 900	55

The best data-split was investigated using the Akaike Information Criteria (AIC) on a number of potential regressions. Four indices were subsequently used: pre- and post-GPS in the east and the west areas. These two areas are very distinct: the west consists of flat fishing and the east of hill fishing, the west area was first fished 10 years prior to the east, and there has been a move by the fishery since the early 1990s from the west to the east. However, despite all these differences, for each area the two series present almost identical patterns of decline in relative standardised CPUE from the time exploitation started in earnest (1980 in the west and 1992 in the east) which would suggest that for this fishery, CPUE might be a reasonable index of abundance.

The standardised CPUE series and CVs are described in Table 2. Over comparable time periods and data sets, the trends from the updated series were similar to those from the 2000 analyses (Coburn et al 2001b). The west CPUE reduced to between 5% of 1980 value and 15% of 1981 value by 1990. The post-GPS west series is either flat or slightly increasing. The east CPUE reduced to 4% of 1984 value and 21% of 1985 value by 1990 even though catches were low. The post-GPS east series showed a further steep initial decline with total reduction to 15% of 1993 values by 2008.

Table 2: OEO 4 black oreo standardised CPUE analyses in 2009 (expressed in t / tow).

fishing year	pre-GPS east		pre-GPS west		fishing year	post-GPS east		post-GPS west	
	index	cv	index	cv		index	cv	index	cv
1980			8.97	0.17	1993	0.71	0.15	0.73	0.41

					2008	0.10	0.09	0.88	0.24

Relative abundance estimates from trawl surveys

The estimates, and their CVs, from the four standard *Tangaroa* south Chatham Rise trawl surveys are treated as relative abundance indices (Table 3).

Table 3: OEO 4 black oreo research survey abundance estimates (t). N is the number of stations. Estimates were made using knife-edge recruitment set at 33 cm TL. Previously knife-edge recruitment was set at 27 cm and estimates of abundance based on that value are also provided for comparison.

Year	Mean abundance		CV (%)	N
	27 cm	33 cm		
1991	34 407	13 065	40	105
1992	29 948	12 839	46	122
1993	20 953	6 515	30	124
1995	29 305	9 238	30	153

Observer length frequencies

Observer length frequencies were available for about 20% of the yearly catch from 1989 to 2008. Analyses conducted on these data indicated that they were not representative of the spatial spread of the fishery. When stratified by depth, the length frequencies had double-modes, centred around 28 cm

and 38 cm, with inconsistent trends in the modes between years. Alternative stratification by subarea, hill, etc, did not resolve the problem; some tows showed bimodality. These patterns in length frequencies were an issue because the yearly shifts in length frequencies and double mode cannot be representative of the underlying fish population since black oreo is a slow growing long-lived fish. They are more likely linked with discrete spatial sub-groups of the population.

A similar double mode was reported for some strata in the same area in the 1994 *Tangaroa* trawl survey (Tracey & Fenaughty 1997). It is likely that there is further spatial structure in the stock that is currently unaccounted for.

4.2.2 Biomass estimates

The 2009 stock assessment of OEO 4 black oreo was inconclusive as assessment models were unable to represent the observer length frequency structure, and were considered unreliable. The CPUE was fitted satisfactorily under a two-stock model but could not be fitted in a single homogeneous stock model. However, the WG agreed that:

1. The CPUE indices are consistent with a two-stock structure or at least a minimally-mixing single stock.
2. The updated CPUE estimates were probably a reasonable indicator of abundance (at the spatial scale of the east and west analyses).

4.2.3 Yield estimates and projections

In 2000, MCY was estimated using the equation, $MCY = c * Y_{AV}$ (Method 4). There was no trend in the annual catches, nominal CPUE, or effort from 1982–83 to 1987–88 so that period was used to calculate the MCY estimate (1200 t). The MCY calculation was not updated in 2009.

CAY cannot be estimated because of the lack of current biomass estimates.

4.3 Smooth oreo

Biomass and yield estimates for smooth oreo were made using a CASAL age-structured population model with Bayesian estimation, incorporating deterministic recruitment, life history parameters (see Table 1 of the Biology section at the beginning of the Oreos report), and catch history up to 2009–10. Data fitted in the model included acoustic survey abundance estimates, standardised CPUE indices, observer length data from the commercial fishery and the acoustic survey length data. In previous assessments (Doonan et al 2001a, 2003, 2008), the stock area was split at 178° 20' W into a west and an east fishery based on an analysis of research trawl results and commercial catches.

The 2012 assessment initially updated the base case of the 2007 assessment with recent catch data, a new acoustic absolute abundance estimate from a survey carried in 2009, updated observer length data, standardised CPUE and length data from the acoustic survey. The updated model had similar results to the previous assessment, with current spawning biomass estimated to be about 46% of the virgin level. However, some of the issues seen in previous assessments remained: the length frequency data seemed to be in conflict with the abundance data; the west post-GPS standardised CPUE showed an opposite trend to the east CPUE and was inconsistent with the acoustic abundance indices.

Oreo catches have shown marked changes in fishing patterns over time. Large catches first started in the west and then progressed east over time and appeared to represent successive exploitation of new areas. Previously exploited areas in the west did not sustain high catches over time. The target species and the type of fishing also changed over time with smooth oreo the target species in the west on flat, dropoff, and seamounts from the late 1970s, with a gradual change to target fishing for orange roughly on seamounts in the east from the late 1980s. Since the late 1990s, there has been an increase in target fishing for smooth oreo in the east, with more fish being caught as a target species than as bycatch. Given these changes in the fishery, the Deepwater Working Group decided that using CPUE as an index of abundance should be discontinued.

OREOS (OEO 4)

With no CPUE indices being included, the 2012 assessment could be simplified into a one area model using just the acoustic abundances. To limit the extra uncertainty in “layer” marks which contained the pre-recruited fish, the abundance estimates were re-calculated as vulnerable abundance. Selectivities for both the commercial fishery and acoustic survey were assumed to be length-based and knife-edged at 33 cm based on the distribution of the observer length commercial data. Acoustic abundance data were fitted as relative abundances using a log-normal likelihood with no additional process error. The model assumed a fixed M (0.063).

Three sets of indices of vulnerable abundance were calculated: two were based on the ratio of adult to total biomass calculated using the length data from the surveys and assuming a length cut-off of 33 or 34 cm, and the other was based on the acoustic mark types that are fished for smooth oreo. Two model runs were reported: model 3.2 was fitted to the time series based on the length cut-off of 33 cm and model 5.2 was fitted to the time series based on the fished marks (Table 4). An alternative model using the length cut-off of 34 cm produced similar results to model 3.2 and therefore was not reported.

Informed priors were assumed for the survey catchability coefficient (q). For the time series based on fished marks, a lognormal prior $LN(-0.22, 0.3)$ was assumed. The prior was based on the estimated ranges of a number of factors: the ratio of mean target strength to the true target strength of smooth oreo (approximately a factor of 1.58), the ratio of the QMA scaling-factor to true scaling-factor which was used to scale to acoustic abundance estimate from the acoustic survey area to the QMA area (approximately 1.11 with a range between 1.03 and 1.25), and the proportion of vulnerable biomass in the adult acoustic marks estimated from the ratio of adult abundance estimates based on the 33 cm length cut-off and estimates based on fished marks from the four surveys (approximately 0.8 with a range between 0.6 and 1.0). Combining the three factors, the median value for the prior on q was estimated to be 0.8 and the range between 0.34 and 1.71, and this can be represented very closely by a lognormal distribution $LN(-0.22, 0.3)$. For the time series based on the length cut-offs, a lognormal prior $LN(0, 0.3)$ was assumed (which had the median value of 1 but the same CV). The argument being that the additional variance associated with target strength bias in the layers is similar to the variance from the adult-proportion uncertainty (a convenient assumption).

The following assumptions were made in the stock assessment analyses:

- (a) Recruitment was deterministic and followed a Beverton-Holt relationship with steepness of 0.75.
- (b) Catch overruns were 0% during the period of reported catch.
- (c) The population of smooth oreo in OEO 4 was a discrete stock or production unit.
- (d) The catch history was accurate.

Bayesian procedures were used in the assessment to estimate the uncertainties in model estimates of biomass for all model runs using the following procedure:

1. Model parameters were estimated using maximum likelihood and the prior probabilities;
2. Samples from the joint posterior distribution of parameters were generated with the Monte Carlo Markov Chain procedure (MCMC) using the Hastings-Metropolis algorithm;
3. A marginal posterior distribution was found for each quantity of interest by integrating the product of the likelihood and the priors over all model parameters; the posterior distribution was described by its median, 5th and 95th percentiles for parameters of interest.

Bayesian estimates were based on the median of a 5.5 million long MCMC sampled at each 500th value, with the first 10% excluded.

Table 4: Descriptions of the two model runs reported for the 2012 smooth oreo assessment. LN, lognormal distribution with mean and standard deviation (log space) given in the bracket.

Model run	Description
3.2	Adult acoustic estimates using a length cut-off at 33 cm, estimating q with a $LN(0, 0.3)$ prior
5.2	Adult acoustic estimates using the fished marks, estimating q with a $LN(-0.22, 0.3)$ prior

4.3.1 Estimates of fishery parameters and abundance

The 2012 assessment incorporated the catch history and the adult acoustic abundance indices based on either the length cut-off of 33 cm or fished marks. The updated CPUE indices, observer length data, and acoustic length data were not included in the 2012 assessment model.

Catch history

A catch history for OEO 4 was developed by scaling the estimated catch to the QMS values, Table 5.

Table 5: Catch history for OEO 4 smooth oreo (t)

Year	OEO 4	Year	OEO 4
1978–79	1 321	1994–95	6 936
1979–80	112	1995–96	6 378
1980–81	1 435	1996–97	6 359
1981–82	3 461	1997–98	6 248
1982–83	3 764	1998–99	6 030
1983–84	5 759	1999–00	6 357
1984–85	4 741	2000–01	6 491
1985–86	4 895	2001–02	4 291
1986–87	5 672	2002–03	4 462
1987–88	7 764	2003–04	5 656
1988–89	7 223	2004–05	6 473
1989–90	6 789	2005–06	5 955
1990–91	6 019	2006–07	6 363
1991–92	5 508	2007–08	6 422
1992–93	5 911	2008–09	6 090
1993–94	6 283	2009–10	6 118

Absolute abundance estimates from the 1998, 2001, 2005, and 2009 acoustic surveys

Absolute estimates of abundance were available from four acoustic surveys:

- (i) 26 September to 30 October 1998 on *Tangaroa* (voyage TAN9812);
- (ii) 16 October to 14 November 2001 using *Tangaroa* for acoustic work (voyage TAN0117) and *Amatal Explorer* (voyage AEX0101) for trawling;
- (iii) 3–22 November 2005 using *Tangaroa* for acoustic work (voyage TAN0514) and 3–20 November 2005 using *San Waitaki* (SWA0501) for mark identification trawling;
- (iv) 2–18 November 2009 using *Tangaroa* for acoustic work (voyage TAN0910) and 2–18 November 2009 using *San Waitaki* (SWA0501) for mark identification trawling.

Acoustic abundance estimates for total smooth oreo from seamounts and flat for the whole of OEO 4 are in Table 6. The 1998 and 2001 estimates for the mixed species mark-types were adjusted to match the larger contribution for non-smooth oreo species in these mark types from the trawl net used in 2005.

Table 6: Estimated total smooth oreo abundance (t) from acoustic surveys in 1998, 2001, 2005, and 2009 by east, west and for the combined area. CVs are in brackets (%).

	1998	2001	2005	2009
West	22 600 (52)	43 000 (35)	32 200 (31)	28 100 (51)
East	127 000 (37)	183 000 (22)	91 800 (30)	46 900 (35)
Total	146 600 (33)	218 165 (22)	115 500 (28)	66 500 (36)

One of the major uncertainties in the assessment is the amount of smooth oreo estimated to be in the layers (about 72% of the total abundance for the 1998 acoustic survey, 47% for the 2001 survey, about 45% for the 2005 survey, and about 61% for the 2009 survey). The contribution of large (greater than 31 cm) smooth oreo to the total backscatter in these layers was typically less than 10%, with the remainder composed of a number of associated bycatch species and smaller smooth oreo in 1998 and 2001. The contribution made by the suite of other fish species present in the layers adds to the overall uncertainty in the biomass estimates from the assessment. However, the contribution of large smooth oreo to the total backscatter in the schools was typically greater than 75% in 1998 and 2001. Therefore, the smooth oreo abundance estimates from the schools were considered to be better estimated than the equivalent estimates from the layers.

OREOS (OEO 4)

Abundance of vulnerable smooth oreo was estimated using two different methods. The first method used the length cut-off from the surveys determined from a mid-point (33 to 34 cm) of the mode of the commercial length distribution. Biomass estimates were produced for length cut-offs of both 33 and 34 cm. The second method was based on the biomass estimated from only three mark types: deep schools, shallow schools, and hill marks. These estimates were made for the whole area (Table 7).

Table 7: Estimated abundance (t) for the combined area based on a length cut-off of 33 or 34 cm, or on the vulnerable acoustic marks from acoustic surveys in 1998, 2001, 2005, and 2009. CVs are in brackets (%).

Year	Biomass (> 33 cm)	Biomass (> 34 cm)	Biomass (marks)
1998	69 673 (33)	59 855 (33)	65 679 (26)
2001	102 017 (19)	88 417 (19)	81 633 (26)
2005	70 304 (22)	61 056 (22)	63 237 (25)
2009	55 441 (30)	49 760 (31)	26 953 (26)

Observer length frequencies

Observer length data were extracted from the observer database. These data were stratified by season (October–March and April–September) and area (west/east). The length frequencies were combined over strata by the proportion of catch in each stratum.

The scaled length frequencies were used to determine the length cut-offs (above) for estimating the adult abundance, but was not otherwise included in the assessment model

Relative abundance estimates from standardised CPUE analyses

Table 8: OEO 4 smooth oreo time series of combined and positive catch abundance indices from standardised CPUE analyses used in the assessment.

Year	Combined index	Jackknife CV	Year	Combined	Jackknife CV
(a) Target SSO pre-GPS (east + west but mainly west data)			(b) Target OEO/SSO post-GPS (west)		
1981–82	1.40	15	1992–93	0.46	27
1982–83	1.36	19	1995–96	0.50	36
1983–84	1.04	21	1996–97	0.90	15
1984–85	0.84	20	1997–98	0.76	70
1985–86	1.00	44	1998–99	0.74	18

1988–89	0.68	22	2001–02	0.99	47
(c) Bycatch post-GPS (east)			2002–03	1.32	24
1992–93	1.79	37	2003–04	1.25	23
1993–94	1.53	25	2004–05	1.55	28
1994–95	1.38	16	2005–06	1.33	26
1995–96	1.09	60	2006–07	1.22	15
1996–97	1.72	17	2007–08	1.49	12
1997–98	1.10	22	2008–09	1.20	46
1998–99	1.19	24	2009–10	1.27	10
1999–00	1.28	76			
2000–01	1.03	17			
2001–02	0.92	16			
2002–03	1.05	18			
2003–04	1.09	44			
2004–05	0.71	26			
2005–06	0.60	16			
2006–07	0.86	33			
2007–08	0.63	31			
2008–09	0.61	25			
2009–10	0.56	33			

The CPUE analysis method was the same as that described above (Section 4.2) for OEO 4 black oreo except that a revised method was used to convert the index values to a canonical form by dividing each value by the geometric mean of the index series following the suggestion of Francis (1999) resulting in the index value for the reference year being a value other than 1. Annual CVs for the combined indices were estimated using a jackknife technique (Doonan et al 1995) but the method was revised by using the canonical index values to calculate the jackknife CV values and resulted in the reference year CV having a value other than 0. The target SSO pre-GPS series (Table 8a) used data from the both east and west areas but most of the data were from the west. The previous assessment used east and west indices (Table 8 a, b, c) but these are not included in the final 2012 assessment.

4.3.2 Biomass estimates

The final assessment runs presented here are runs 3.2 and 5.2 (Table 4). Estimated parameters for both cases appeared to achieve MCMC convergence.

The estimates of biomass are shown in Table 9 (and Figure 1). The median estimate of current mature biomass was 41% for the model using the abundance series based on the 33 cm length cut-off, and 33% B_0 for the model based on fished marks. The biomass estimates generally have wide 90% confidence bounds (Figure 2).

The vulnerable abundance based on fished marks was similar to that using the length cut-offs for the 1998, 2001, and 2005 surveys, but was much lower for the 2009 survey (Table 7). The reason is not clear but it could be that a considerable proportion of vulnerable biomass was contributed by the layer mark. As a result, current biomass estimates for the model based on fished marks were less optimistic.

Estimated exploitation rates were low but appeared to have steadily increased over recent years (Figure 4). The median of current exploitation rate was estimated to be about 8% for model 3.2 and about 12% for model 5.2.

MPD estimates of survey catchability q were close to the median of the assumed prior and the posterior distributions of q were similar to their prior distributions for both models 3.2 and 5.2 (Figure 5). Model results appeared to be strongly driven by the assumed prior for q ; when the assumed value of q was halved or doubled the posterior distributions from the model were very similar to the prior distributions. The range of estimates for the catchability coefficient q was based on limited information on target strength, the QMA scaling-factor, and the proportion of vulnerable biomass in the vulnerable acoustic marks, and therefore is likely to be imprecise.

The current stock size, $\%B_0$, was estimated to be 26–55% and 18–49% for models 3.2 and 5.2 respectively. These estimated bounds may not represent the true level of uncertainty in the stock assessment. There are a number of structural assumptions in the model that result in the true uncertainty of the model biomass estimates being underestimated. These include the assumption that there was no variability in recruitment (deterministic recruitment was used).

Table 9: Mature biomass, estimates for OEO 4 smooth oreo.

	MCMC 3.2			MCMC 5.2		
	5%	Median	95%	5%	Median	95%

Figure 1: Bayesian posterior distribution of current mature biomass estimates as a percentage of virgin biomass for model 3.2 (left) and 5.2 (right). The black dashed line is the median of the MCMC posterior distribution; the red dashed line is the MPD point estimate.

Figure 2: Bayesian posterior distribution of mature biomass as a percentage of B_0 for model 3.2 (left) and 5.2 (right). Dashed lines represent the target ($40\% B_0$), soft limit ($20\% B_0$), and hard limit ($10\% B_0$) respectively.

Figure 3: MPD fits of the vulnerable abundance time series for model 3.2 (left) and 5.2 (right). Points are the acoustic estimates scaled by catchability coefficient to abundance. Curved lines are the model estimates of biomass (t): solid top line is the abundance that the acoustics measures and dashed line is the mature abundance. Vertical thinner error bars for acoustic are ± 2 S.D., the thicker bars are ± 1 S.D.

4.3.3 Yield estimates and projections

No estimates of *MCY* and *CAY* are available.

Figure 4: Bayesian posterior distribution of exploitation rate for model 3.2 (left) and 5.2 (right).

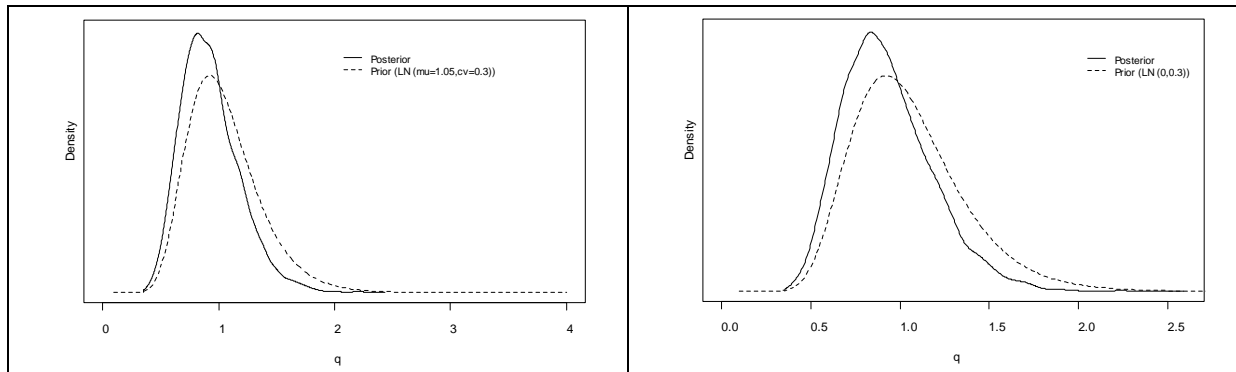

Figure 5: Bayesian posterior distribution of survey catchability q and the prior for model 3.2 (left) and 5.2 (right).

4.3.4 Other factors that may modify assessment results

The WG considered that there were a number of other factors that should be considered in relation to the stock assessment results presented here:

- There are a number of factors that are outside the model and the analyses, that add uncertainty to the model estimates of biomass. These include the sensitivity of the acoustic biomass estimate to the low value of the target strength of smooth oreo, and uncertainty in the estimates of M and growth rates.
- Age frequencies estimated from the 1998 and 2005 acoustic surveys suggest the possibility of poor recruitment to 1 year olds from 1986 up to 1995, the youngest cohort that would be seen in the 2005 acoustic data (Doonan et al 2008). These cohorts would enter the fishery (at about age 23) from 2009 to 2018. However, age data from the 1993 and 1994 trawl surveys on the eastern end of the south Chatham Rise were ambiguous (Doonan & McMillan 2011).
- This assessment suggests that there is no immediate sustainability issue for OEO 4 smooth oreo, but the large decline in the 2009 acoustic abundance indices suggests that future monitoring of the stock would be wise.

5. STATUS OF THE STOCKS

There is a new stock assessment in 2012 for the smooth oreo stock.

Stock Structure Assumptions

The two oreo stocks on the Chatham Rise are assessed separately but managed as a single stock. For black oreos the population has been found to be genetically similar to other oreo stocks and it is likely that some mixing occurs. Smooth oreos in SSO 4 are assumed to be distinct from OEO 1 and OEO 6 stocks but may mix with the 3A stock.

- **OEO 4 (Black Oreos)**

Stock Status	
Year of Most Recent Assessment	2009
Assessment Runs Presented	No quantitative stock assessment model
Reference Points	Target(s): 40% B_0 Soft Limit: 20% B_0 Hard Limit: 10% B_0
Status in relation to Target	Unknown
Status in relation to Limits	Unknown

OREOS (OEO 4)

Historical Stock Status Trajectory and Current Status Unknown

Fishery and Stock Trends	
Recent Trend in Biomass or Proxy	CPUE has been stable for the last five years, after initial substantial decline during the 1980s and 1990s.
Recent Trend in Fishing Mortality or Proxy	Unknown
Other Abundance Indices	-
Trends in Other Relevant Indicators or Variables	-

Projections and Prognosis	
Stock Projections or Prognosis	Unknown
Probability of Current Catch or TACC causing decline below Limits	Soft Limit: Unknown Hard Limit: Unknown

Assessment Methodology	
Assessment Type	Level 2 – Partial quantitative stock assessment
Assessment Method	Age-based model in CASAL
Main data inputs	- Four standardised CPUE indices (pre/post GPS and east/west) - Observer length frequencies
Period of Assessment	Latest assessment: 2009 Next assessment: Unknown
Changes to Model Structure and Assumptions	-
Major Sources of Uncertainty	- Assessments unable to represent observer length frequency data. - CPUE could be fitted to a two-stock model but not a homogenous model. - A portion of the abundance estimates were based on data from areas not normally covered by the trawl fishery, and the surveyed area was scaled by a factor of 4.3 – the area surveyed was borderline for providing a reliable abundance estimate.

Qualifying Comments	
The WG agreed that the stock might be split into east and west areas that were independent or at least minimally mixing for future assessments.	

Fishery Interactions	
Both species of oreo are sometimes taken as bycatch in orange roughy target fisheries and in smaller numbers in hoki target fisheries. Target fisheries for oreos do exist, with main bycatch being orange roughy, rattails and deepwater sharks. Bycatch species of concern include deepwater sharks and rays, seabirds and deepwater corals.	

• **OEO 4 (Smooth Oreos)**

Stock Status	
Year of Most Recent Assessment	2012
Assessment Runs Presented	Two model runs fitted to two alternative vulnerable acoustic abundance estimates (model 3.2 and 5.2)
Reference Points	Target(s): 40% B_0 Soft Limit: 20% B_0 Hard Limit: 10% B_0
Status in relation to Target	B_{2010} was estimated at 41% B_0 for model 3.2, and 33% B_0 for model 5.2. B_{2010} is as likely as not to be at or above the target

Status in relation to Limits	B_{2010} is Unlikely (< 40%) to be below the Soft limit and very Unlikely (< 10%) to be below Hard Limits
------------------------------	---

Historical Stock Status Trajectory and Current Status

Spawning stock biomass trajectory for model 3.2 (left) and 5.2 (right).

Fishery and Stock Trends

Recent Trend in Biomass or Proxy	Biomass appears to be steadily decreasing
Recent Trend in Fishing Mortality or Proxy	Estimated exploitation rates were low but appeared to have steadily increased over recent years
Other Abundance Indices	-
Trends in Other Relevant Indicators or Variables	Age frequencies estimated from the 1998 and 2005 acoustic surveys suggest the possibility of poor recruitment into the fishery from 2009 to 2018.

Projections and Prognosis

Stock Projections or Prognosis	No model projections were made due to uncertainty in the assessment, however, there is concern that the current downward trend may continue.
Probability of Current Catch or TACC causing decline below Limits	Soft Limit: Unknown Hard Limit: Unknown
Probability of Current Catch or TACC causing Overfishing to continue or to commence	

Assessment Methodology and Evaluation

Assessment Type	Type 1 – Quantitative Stock Assessment	
Assessment Method	Age-structured CASAL model with Bayesian estimation of posterior distributions	
Assessment Dates	Latest assessment: 2011	Next assessment: Unknown
Overall assessment quality rank	2 – Medium or Mixed Quality: assessment results are strongly driven by the assumed prior on q	
Main data inputs (rank)	- Four estimates of abundance from acoustic surveys (1998, 2001, 2005, 2009) - Observer length data (not used, except to provide a length cut off for vulnerable fish)	1 – High Quality 1 – High Quality
Data not used (rank)	Commercial CPUE	3 – Low Quality: the nature of the fishery has changed over time, particularly the ratio of targeting to bycatch
Changes to Model Structure and Assumptions	Simplified to a single-area, single fishery model with deterministic recruitment	
Major Sources of Uncertainty	Recruitment assumed to be deterministic. Uncertainties in the assumptions used to determine the prior for the survey catchability (q):	

OREOS (OEO 4)

	<ul style="list-style-type: none">• estimated target strength• scaling factor from the trawl survey area to acoustic area• scaling factor from acoustic area to the QMA area• proportion of vulnerable biomass in the fished marks
--	---

Qualifying Comments

The biomass estimate based on adult marks declined in the 2009 survey

Fishery Interactions

Both species of oreo are sometimes taken as bycatch in orange roughy target fisheries and in smaller numbers in hoki target fisheries. Target fisheries for oreos do exist, with main bycatch being orange roughy, rattails and deepwater sharks. Bycatch species include deepwater sharks and rays, seabirds and deepwater corals.

OREOS - OEO 1 AND OEO 6 BLACK ORO AND SMOOTH ORO

1. FISHERY SUMMARY

This is presented in the Fishery Summary section at the beginning of the Oreos report.

2. BIOLOGY

This is presented in the Biology section at the beginning of the Oreos report.

3. STOCKS AND AREAS

This is presented in the Stocks and Areas section at the beginning of the Oreos report.

4. STOCK ASSESSMENT

4.1 Introduction

New assessments for Pukaki Rise black oreo and Pukaki Rise smooth oreo were attempted in 2013 but were rejected by the Working Group and are only briefly discussed here. The previously reported assessments for Southland (OEO 1/OEO 3A) and Bounty Plateau smooth oreo (only MPD results) are repeated.

4.2 Southland smooth oreo fishery

This assessment was updated in 2007 and applies only to the study area as defined in Figure 1 and does not include areas to the north (Waitaki) and east (Eastern canyon) of the main fishing grounds.

This fishery is mostly in OEO 1 on the east coast of the South Island but catches occur at the northern end of the fishery straddle and cross the boundary line between OEO 1 and OEO 3A at 46°S. This is an old fishery with catch and effort data available from 1977–78. Smooth oreo catch from Southland was about 480 t (mean of 2003–04 to 2005–06). There is an industry catch limit of 400 t smooth oreo implemented after the previous (2003) assessment. There were no fishery-independent abundance estimates, so relative abundance estimates from pre- and post-GPS standardised CPUE analyses and length frequency data collected by Ministry (SOP) and industry (ORMC) observers were used.

The following assumptions were made in this analysis.

1. The CPUE analysis indexed the abundance of smooth oreo in the study area of OEO 1/3A.
2. The length frequency samples were representative of the population being fished.
3. The ranges used for the biological values covered their true values.
4. Recruitment was deterministic and followed a Beverton-Holt relationship with steepness of 0.75.
5. The population of smooth oreo in the study area was a discrete stock or production unit.
6. Catch overruns were 0% during the period of reported catch.
7. The catch histories were accurate.
8. The maximum fishing pressure (U_{MAX}) was 0.58.

An age-structured CASAL model employing Bayesian statistical techniques was developed. A two-fishery model was employed with a split into deep and shallow fisheries because of a strong relationship found between smaller fish in shallow water and large fish in deeper water. The boundary between deep and shallow was 975 m. The 2007 analysis used five extra years of catch and observer length frequency data compared to the 2003 assessment. The model was partitioned by the sex and maturity status of the fish and used population parameters previously estimated from fish sampled on the Chatham Rise and Puysegur Bank fisheries. The maturity ogive used was estimated from Chatham Rise research samples.

4.2.1 Estimates of fishery parameters and abundance

Catch history

A catch history (Table 1) was derived using declared catches of OEO from OEO 1 (see table 2 in the Fishery Summary section at the beginning of the Oreos report) and tow-by-tow records of catch from the study area (Figure 1). The tow-by-tow data were used to estimate the species ratio (SSO/BOE) and therefore the SSO taken. It was assumed that the reported landings provided the best information on total catch quantity and that the tow-by-tow data provided the best information on the species and area breakdown of catch.

Table 1: Catch history of smooth oreo from Southland rounded to the nearest 10 t.

Fishing year	Shallow	Deep	Fishing year	Shallow	Deep
1977-78	210	0	1992-93	410	250
1978-79	10	0	1993-94	220	150
1979-80	40	0	1994-95	80	150
1980-81	0	0	1995-96	600	500
1981-82	0	0	1996-97	440	70
1982-83	0	0	1997-98	320	230
1983-84	480	660	1998-99	480	620
1984-85	170	510	1999-00	650	480
1985-86	480	3 760	2000-01	400	610
1986-87	30	160	2001-02	580	1 470
1987-88	130	860	2002-03	130	1 320
1988-89	0	240	2003-04	330	420
1989-90	210	430	2004-05	140	290
1990-91	410	420	2005-06	120	140
1991-92	530	380			

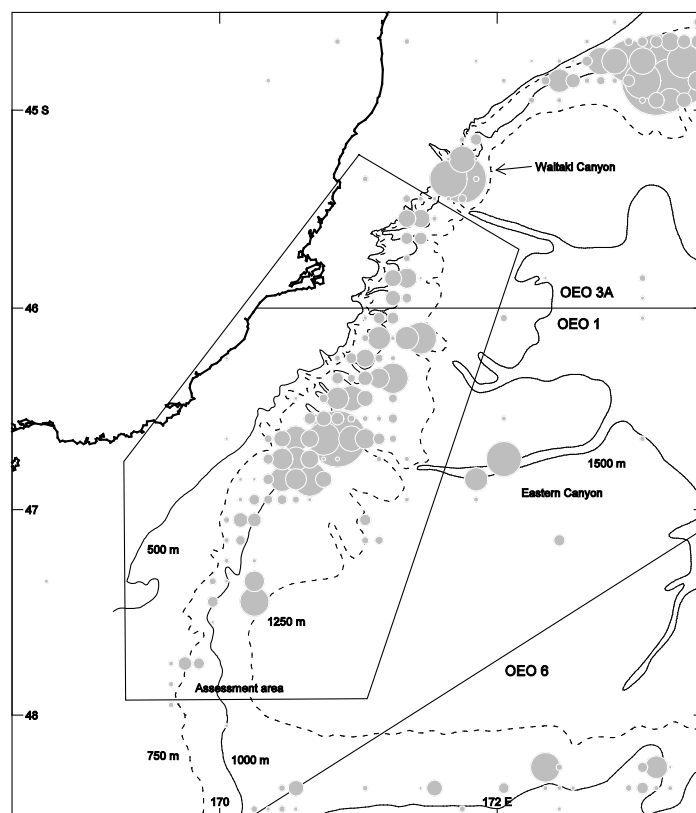

Figure 1: Smooth oreo estimated catch from all years up to (and including) 2005-06. The area was divided into cells that are 0.1 degrees square and catches were summed for each cell. Circles proportional in area to the catch are plotted centred on the cells. Catches less than 10 tonnes per cell are not shown. Circles are layered so that smaller circles are never hidden by larger ones. The assessment area and bottom topography are also shown.

Length data

All SOP records where smooth oreo were measured from within the assessment area are shown in Table 2: 78 samples were shallow and 51 deep. Only 13 shallow and 4 deep samples were collected before 1999–2000 (Table 2). Composite length frequency distributions were calculated for each year. Each sample was weighted by the catch weight of the tow from which the sample was taken. This was modified slightly by estimating the number of fish that would be in a unit weight of catch and multiplying by that.

Table 2: Summary of length frequency data for smooth oreo available for the study area. Year group, year applied, and the total number of length frequency samples for the shallow and deep year groups.

Year group	Year applied	No. of lfs
<u>Shallow</u>		
a=1993–94 to 1997–98	1995–96	13
b=1999–2000	1999–00	30
c=2000–01 to 2001–02	2001–02	22
d=2002–03 to 2005–06	2004–05	13
<u>Deep</u>		
e=1997–98 to 2001–02	2001–02	27
f=2002–03 to 2004–05	2003–04	21

Relative abundance estimates from CPUE analyses

The standardised CPUE analyses used a two part model which separately analysed the tows which caught smooth oreo using a log-linear regression (referred to as the positive catch regression) and a binomial part which used a Generalised Linear Model with a logit link for the proportion of successful tows (referred to as the zero catch regression). The binomial part used all the tows, but considered only whether or not the species was caught and not the amount caught. The yearly indices from the two parts of the analysis (positive catch index and zero catch index) were multiplied together to give a combined index. The pre-GPS data covered the years from 1983–84 to 1987–88, was left unmodified from 2003, and was used as an index of the deep fishery as most fishing in that period was deep (Table 3). The post-GPS data covered 1992–93 to 2005–06 split into shallow and deep fisheries but the indices for the last two years (2004–05, 2005–06) were dropped because catch was constrained by the industry catch limit of 400 t for smooth oreo introduced after the 2003 assessment (Table 4).

Table 3: Smooth oreo pre-GPS combined index estimates by year, and jackknife CV estimates from analysis of all tows in the study area that targeted smooth oreo, black oreo, or unspecified oreo.

Year	Combined index	Jackknife CV (%)
1983–84	1.75	22
1984–85	1.65	29
1985–86	1.19	33
1986–87	0.48	23
1987–88	0.61	27

Table 4: Smooth oreo post-GPS combined index estimates by year, and jackknife CV estimates from analysis of all tows in the study area that targeted smooth oreo, black oreo, or unspecified oreo.

Fishing year	Shallow		Deep	
	Index (kg/tow)	Bootstrap CV (%)	Index (kg/tow)	Bootstrap CV (%)
1992–93	1 489	57	1 401	73
1993–94	956	47	916	53
1994–95	1 521	72	428	121

1998–99	939	42	915	50
1999–00	842	44	611	48
2000–01	758	46	385	72
2001–02	573	44	658	53
2002–03	303	48	406	76
2003–04	480	57	719	218

4.2.2 Biomass estimates

Biomass estimates were made based on a Markov Chain Monte Carlo analysis which produced a total of about 1.4 million iterations. The first 100 000 iterations were discarded and every 1000th point was retained, giving a final converged chain of about 1300 points.

Biomass estimates for the base case are given in Table 5 and Figure 2. These biomass estimates are uncertain because of the reliance on commercial CPUE data for abundance indices.

Table 5: Biomass estimates (t) for the base case.

	5%	Median	Mean	95%	CV (%)
Free parameters					
Virgin mature biomass (B_0)	15 600	17 400	17 900	21 700	12
Selectivity, shallow	a1	17.2	19.0	21.0	6
	sL	3.9	4.8	4.8	12
	sR	5.9	8.3	8.4	20
Selectivity, deep	a50	22.1	26.2	30.8	10
	to95	1.9	7.1	7.0	11.0
Derived quantities					
Current mature biomass (% initial)	19	27	28	41	25
Current selected shallow biomass (% initial)	56	65	65	73	8
Current selected deep biomass (% initial)	12	20	22	36	36

Figure 2: Estimated biomass trajectories from the 2007 base case assessment — mature biomass and selected biomass for the shallow and deep fisheries. Also shown are the CPUE indices from the pre- and post-GPS analysis for the deep fishery (in gray) and the post-GPS analyses for the shallow fishery (in black). CPUE indices are shown with ± 2 s.e. confidence interval indicated by the vertical lines (the post-GPS CPUE data are slightly offset to avoid over plotting). The CPUE data were scaled by catchability coefficients to match the biomass scale.

4.3 Pukaki Rise smooth oreo fishery (part of OEO 6)

A second assessment for this fishery was attempted in 2013, applying only to the assessment area as defined in Figure 3. The first assessment for this fishery was in 2006–07 (Coburn et al 2007; McKenzie, 2007). This is the main smooth oreo fishery in OEO 6 with an annual catch in 2011–12 of 290 t, taken mainly by New Zealand vessels, down substantially from previous years (Table 6). There was also a small early Soviet fishery (1980–81 to 1985–86) with mean annual catches of less than 100 t. There were no fishery-independent abundance estimates, so relative abundance estimates from a post-GPS standardised CPUE analysis and length frequency data collected by Ministry and industry observers were considered. Biological parameter values estimated for Chatham Rise and Puysegur Bank smooth oreo were used in the assessment because there are no research data from Pukaki Rise. However, the CPUE analysis was not accepted as an index of abundance for smooth oreo in the Pukaki Rise (OEO 6) assessment area, principally due to the complex temporal and spatial patterns of this fishery and associated fisheries, and the small number of vessels. As a result, the assessment was not accepted by the Working Group, and only catch history, length frequencies and unstandardised catch and effort data are reported here.

Figure 3: The Pukaki Rise fishery assessment area (polygon) abutting the north boundary of OEO 6. The dots show all tows where the target species or catch was OEO, SSO, BOE or ORH, with the red dots being those within the Pukaki assessment area.

4.3.1 Estimates of fishery parameters and abundance

Catch history

A catch history was derived using declared catches of OEO from OEO 6 (Table 2 in the “Fishery Summary” section of the Oreos report above) and tow-by-tow records of catch from the assessment area (Figure 3). The tow-by-tow data were used to estimate the species ratio (SSO/BOE) and therefore the amount of SSO taken. It was assumed that the reported landings provided the best information on total catch quantity and that the tow-by-tow data provided the best information on the species and area breakdown of catch. There may be unreported catch from before records started, although this is thought to be small. Before the 1983–84 fishing year the species catch data were combined over years to get an average figure that was then applied in each of those early years. For the years from 1983–84 onwards, each year’s calculation was made independently. The catch history used in the population model is given in Table 6.

OREOS (OEO 1&6)

Table 6: Catch history of smooth oreo from the Pukaki Rise fishery assessment area. Catches are rounded to the nearest 10 t.

Year	Catch	Year	Catch	Year	Catch	Year	Catch
1980–81	30	1988–89	0	1996–97	1 650	2004–05	1 370
1981–82	20	1989–90	0	1997–98	1 340	2005–06	1 470
1982–83	0	1990–91	10	1998–99	1 370	2006–07	1 790
1983–84	640	1991–92	0	1999–00	2 270	2007–08	1 260
1984–85	340	1992–93	70	2000–01	2 580	2008–09	1 200
1985–86	10	1993–94	0	2001–02	2 020	2009–10	770
1986–87	0	1994–95	130	2002–03	1 340	2010–11	820
1987–88	180	1995–96	1 360	2003–04	1 660	2011–12	290
						2012–13	136

Length data

Smooth oreo length frequency data collected by observers are available from the last 15 years (Table 7). An in-depth analysis of these data in the previous assessment (covering fishing years 1998–2005) indicated that they were reasonably representative of the fishery in terms of spatial, depth and temporal coverage in those years that had adequate data (Coburn et al 2007). The depths fished by the sampled fleet varied between years so the length data were stratified by depth resulting in shallow (less than 900 m), middle (900–990 m) and deep strata (greater than 990 m). The data from adjacent years were also grouped because some years had few samples. The resulting length frequencies are shown in Figure 4. There is a trend towards a flatter distribution over the last three grouped distributions (2000–01, 02, and 03–05).

Table 7: Summary of length frequency data for smooth oreo available for the assessment area. The table shows the number of tows sampled by year, the sample source, and the year group. -, no data.

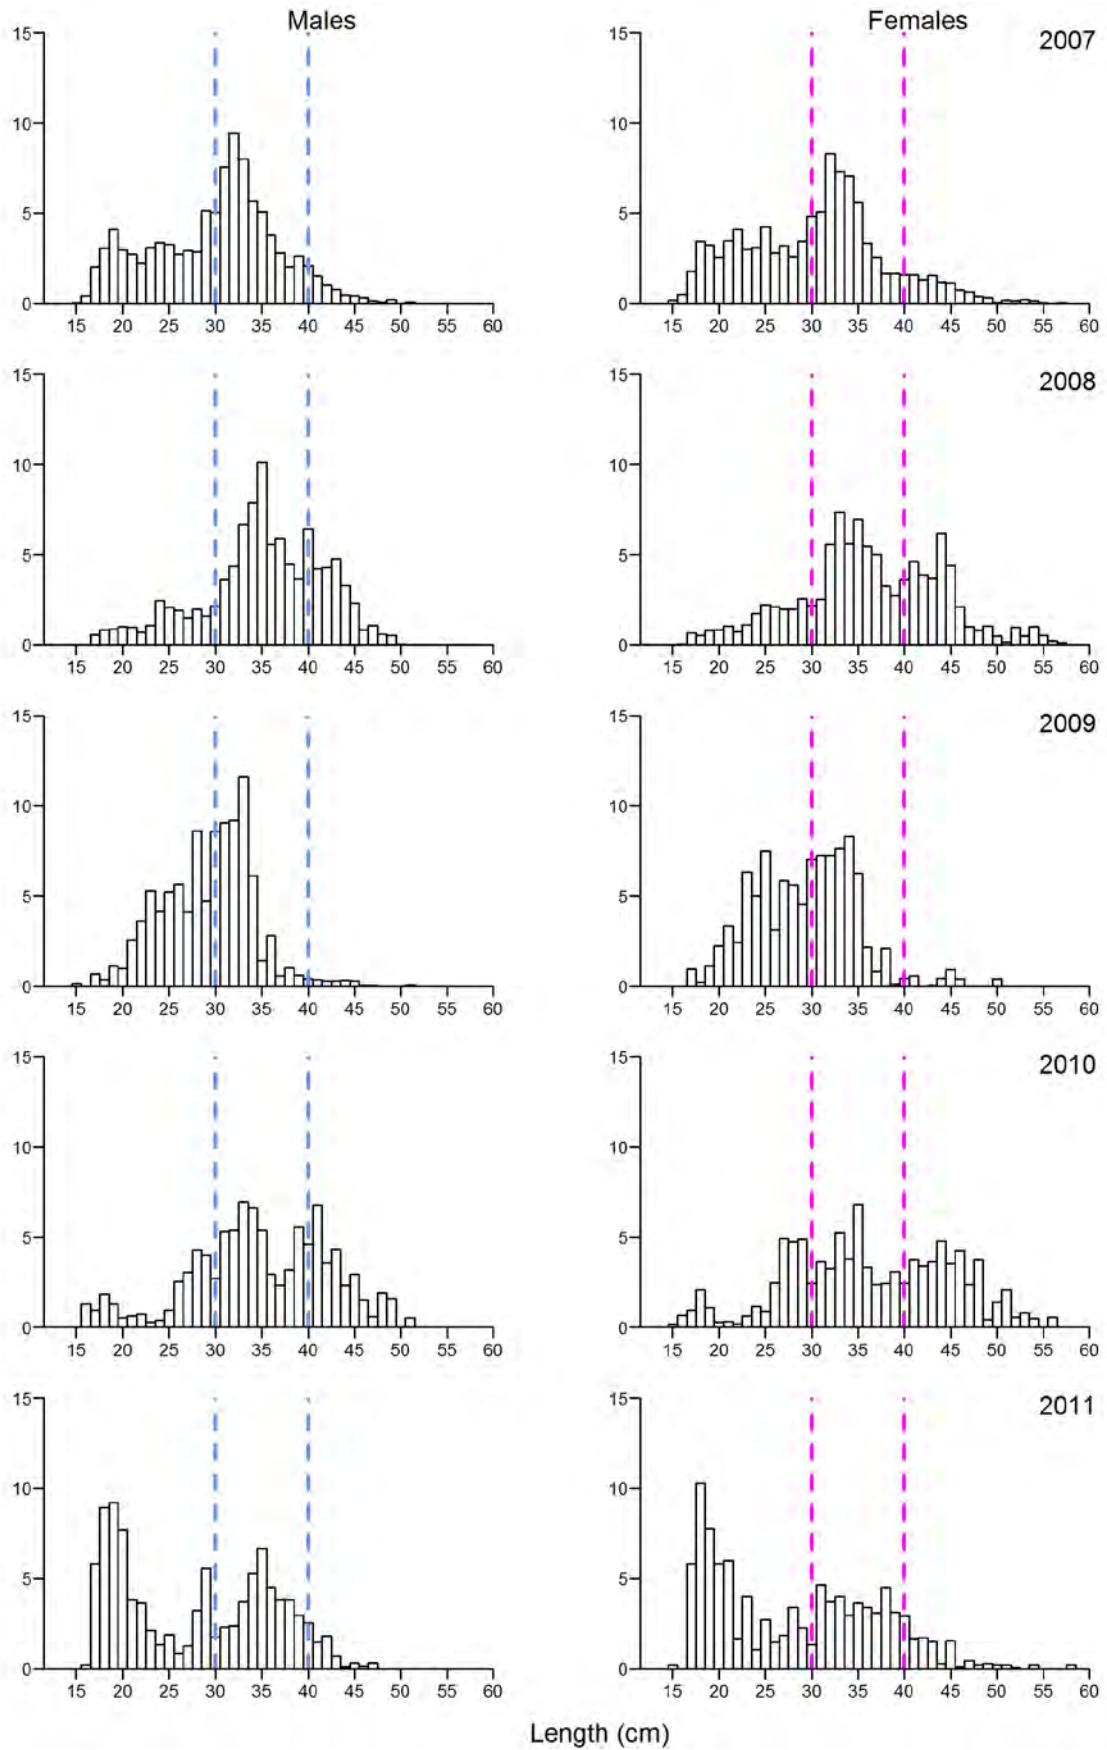

Figure 4 [Continued].

Catch and effort data

Core vessels for the fishery were defined in order to develop a standardised CPUE series, but the standardised series was rejected by the Working group. Unstandardised catch and effort data are presented in Table 8.

Table 8: Catch and effort data for vessels with three or more consecutive years with at least 10 records from 1995–96 to 2011–12.

	No. of tows	No. of vessels	Estimated catch (t)	Mean t/tow	Zero catch tows (%)	SSO target (%)

4.4 Bounty Plateau smooth oreo fishery (part of OEO 6)

The first assessment for this fishery was developed in 2008 and applies only to the study area as defined in Figure 5. There were no fishery-independent abundance estimates, so relative abundance estimates from a post-GPS standardised CPUE analysis and length frequency data collected by Ministry (SOP) and industry (ORMC) observers were considered. Biological parameter values estimated for Chatham Rise and Puysegur Bank smooth oreo were used in the assessment because there are no research data from Bounty Plateau.

The following assumptions were made in this analysis.

1. The CPUE analysis indexed the abundance of smooth oreo in the Bounty Plateau (OEO 6) assessment area.
2. The length frequency samples were representative of the population being fished.
3. The biological parameters values used (from other assessment areas) are close to the true values.
4. Recruitment was deterministic and followed a Beverton & Holt relationship with steepness of 0.75.
5. The population of smooth oreo in the assessment area was a discrete stock or production unit.
6. Catch overruns were 0% during the period of reported catch.
7. The catch histories were accurate.
8. The maximum exploitation rate (E_{MAX}) was 0.58.

Data inputs included catch history, relative abundance estimates from a standardised CPUE analysis, and length data from SOP and ORMC observers. The observational data were incorporated into an age-based Bayesian stock assessment (CASAL) with deterministic recruitment to estimate stock size. The stock was considered to reside in a single area, with a partition by sex. Age groups were 1–70 years, with a plus group of 70+ years.

The length-weight and length-at-age population parameters are from fish sampled on the Chatham Rise and Puysegur Bank fisheries (Table 1, Biology section). The natural mortality estimate is based on fish sampled from the Puysegur Bank fishery. The maturity ogive is from fish sampled on the

Chatham Rise, and the age at which 50% are mature is between 18 and 19 years for males and between 25 and 26 years for females.

4.4.1 Estimates of fishery parameters and abundance

Catch history

Table 9: Catch history (t) of smooth oreo from the Bounty Plateau fishery assessment area. Catches are rounded to the nearest 10 t.

Year	Catch	Year	Catch
1983–84	620	1996–97	610
1984–85	0	1997–98	650
1985–86	0	1998–99	1 200
1986–87	0	1999–00	870
1987–88	10	2000–01	550
1988–89	0	2001–02	980
1989–90	0	2002–03	1 530
1990–91	20	2003–04	1 420
1991–92	0	2004–05	2 190
1992–93	110	2005–06	1 790
1993–94	490	2006–07	670
1994–95	1 450	2007–08	670
1995–96	900		

A catch history was derived using declared catches of oreo from OEO 6 (Table 2 in the “Fishery Summary” section of the Oreos report above) and tow-by-tow records of catch from the assessment area (Figure 5). The tow-by-tow data were used to estimate the species ratio (SSO/BOE) and therefore the SSO taken. The catch history used in the population model is given in Table 9.

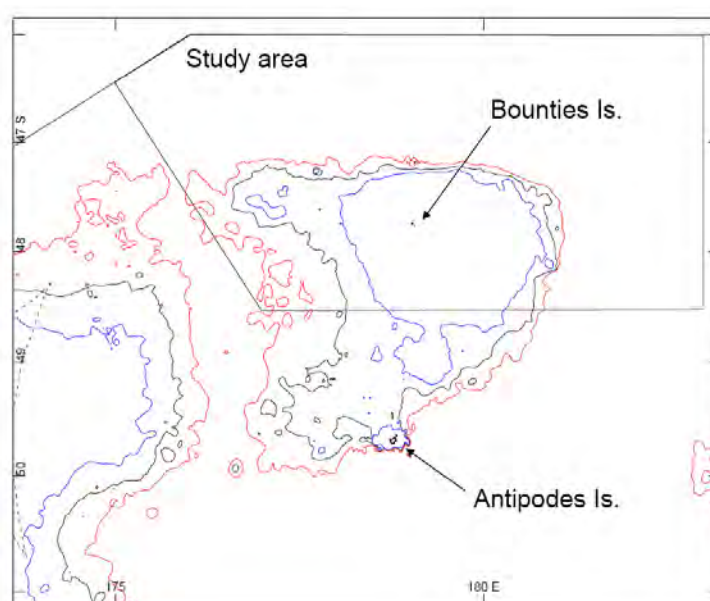

Figure 5: The Bounty Plateau fishery assessment study area.

Length data

Smooth oreo length frequency data collected by SOP and ORMC observers are available from the last twenty eight years. An in-depth analysis indicated that these data were reasonably representative of the fishery in terms of spatial, depth and temporal coverage in those years that had adequate data. Length frequencies were based on tows from the core area (a subset of the study area where about 80% of the catch is take). The data from adjacent years were grouped because some years had few samples (Table 10). The resulting length frequencies are shown in Figure 6. In the final model runs the 1994–95 year of the length frequency series was omitted as it contained very few samples.

Table 10: Core length analysis Year group, year applied and the number of length frequency samples. Smooth oreo sample catch weight, fishery catch and sample catch as percentage of the fishery.

Year group	Year applied	No. of lfs	Catch sampled (t)	Fishery catch (t)	% fishery sampled
1991–92 to 1995–96	1994–95	7	88	1 505	6
1998–99 to 1999–2000	1998–99	30	246	1 121	22
2000–2001 to 2002–03	2001–02	25	398	2 261	18
2003–04 to 2004–05	2004–05	29	261	2 280	11
2005–06	2005–06	32	379	1 121	34
2006–07 to 2007–08	2006–07	17	168	494	34

Relative abundance estimates from CPUE analyses

The small early Soviet fishery had too few data for a standardised CPUE analysis. The standardised CPUE analysis was, therefore, from the New Zealand vessel fishery and only included data from those vessels that had fished at least three years. Just a single vessel puts in significant continuous effort from 1995–2007, with the rest of the vessels’ effort confined to mainly either 1995–2000 (early) or 2001–2007 (late). Because of this, in addition to the single standardised CPUE covering the entire time period, two separate standardised CPUE indices were calculated covering the early and late periods. The final indices are shown in Tables 11 and 12.

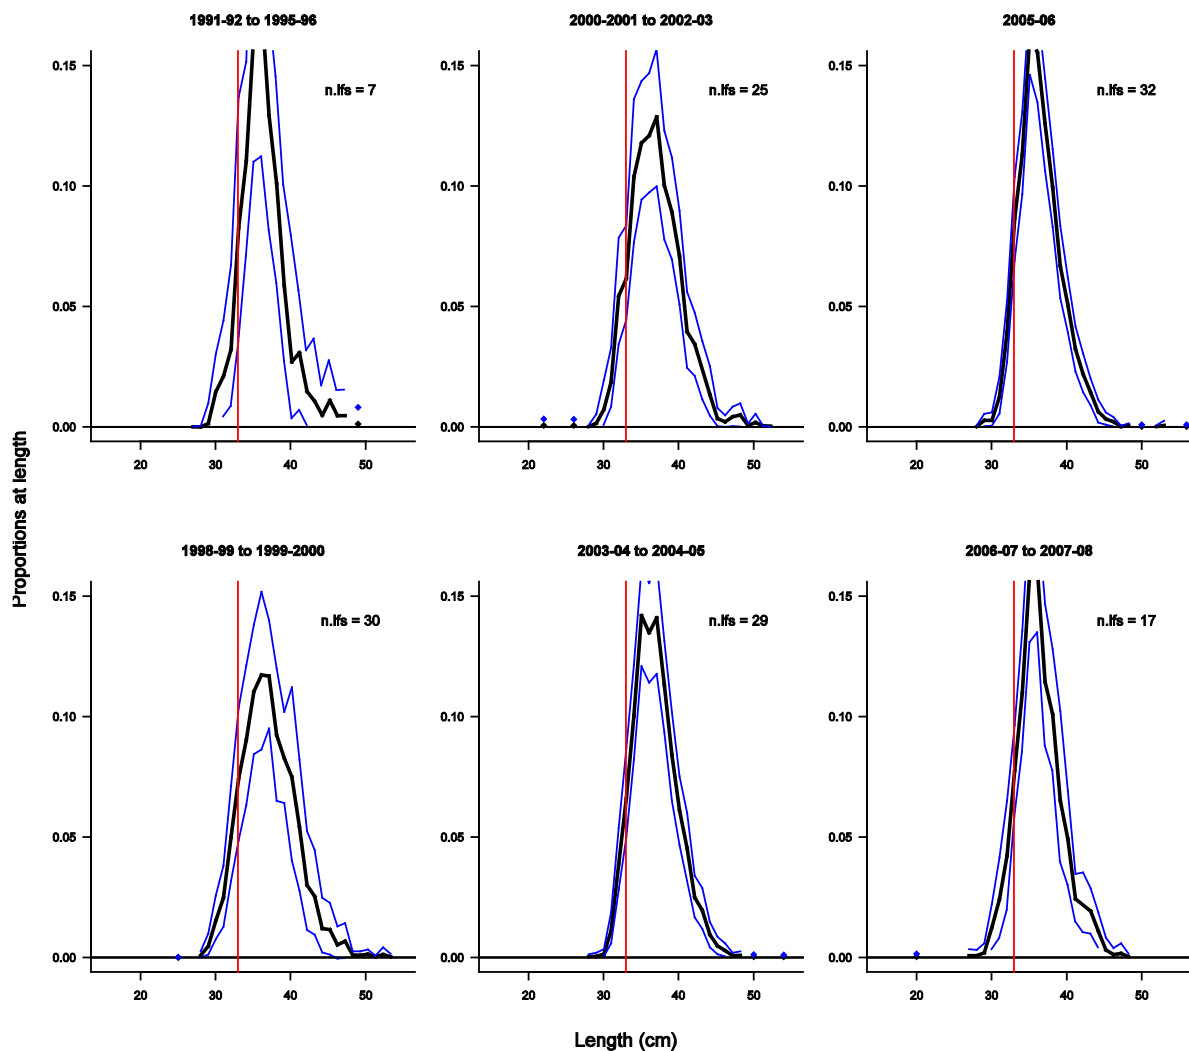

Figure 6: Length frequency distribution plots for core data only (thick lines) with 95% confidence interval (thin lines).

Table 11: Early and late period CPUE combined index estimates by year, and bootstrap CV estimates.

Year	Kg/tow	CV	Late period	Kg/tow	CV
1995-96	3551	0.423	2000-01	850	0.487

2006-07	1056	1.200

4.4.2 Biomass estimates

In all preliminary model runs the length-frequency data series were not well fitted, and gave a strong but contrasting biomass signal relative to the CPUE indices. Therefore, for final model runs, the length frequency data was down-weighted by using just the 1999 length frequency.

The base case model used early and late period CPUE indices, and the 1999 length frequency data. Current mature biomass was estimated to be 33% of a virgin biomass of 17 400 t (Figure 7).

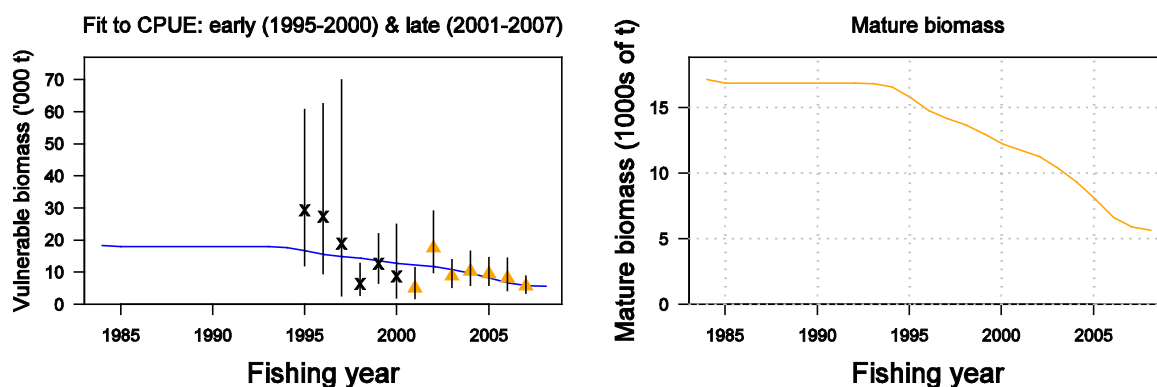

Figure 7: Model run showing the MPD fit to the CPUE data (vertical lines are the 95% confidence intervals for the indices) and the trajectory of mature biomass.

Two sensitivity model runs were carried out with the 1999 length frequency data dropped from the model, but retaining the fishery selectivity estimated using the length data. The first model run used the early and late period CPUE indices and current biomass was estimated to be 39% of a virgin biomass of 19 300 t. The second model run used the single CPUE series covering the same period and current biomass was estimated to be 17% of a virgin biomass of 13 900 t. No MCMC runs were carried out with the base case model as the sensitivity runs showed that the assessment was quite different if the CPUE analysis was not split into two series.

Biomass estimates are uncertain because of the reliance on commercial CPUE data, the use of biological parameter estimates from other oreo stocks, and because of contrasting biomass signals from using either a single or split CPUE indices.

4.4.3 Projections

No projections were made because of the uncertainty in the assessment.

4.5 Pukaki Rise black oreo stock (part of OEO 6)

A second assessment for this fishery was attempted in 2013, applying only to the assessment area as defined in Figure 8. The first assessment for this fishery was in 2009 (Doonan et al 2010). This is currently the largest black oreo fishery in the New Zealand EEZ with both current (2011–12) and mean (1994–95 to 2011–12) annual catches of 1900 t, but with annual catches of 2800–3400 t between 2005–06 and 2009–10. There was an early Soviet and Korean fishery (1980–81 to 1984–85) with mean annual catches of about 1700 t. Fishery-independent abundance estimates were not available, so a series of relative abundance indices, based on an analysis of post-GPS standardised CPUE, was developed. Length frequency data collected by Ministry (SOP) and industry (ORMC) observers were included in the model. The assessment used biological parameter values estimated for Chatham Rise and Puysegur Bank black oreo because no biological data from Pukaki Rise are available. As stated above, the Pukaki Rise smooth oreo CPUE was thought to be unreliable until further investigations have been conducted. Since the black oreo fishery is in the same area, the Working Group determined that the black oreo CPUE analysis also could not be accepted as an index of abundance of black oreo in the Pukaki Rise (OEO 6) assessment area, and as a result the assessment was rejected. Therefore, only catch history, length frequencies and unstandardised catch and effort data are reported here.

4.5.1 Estimates of fishery parameters and abundance

Catch history

A catch history for black oreo was derived (Table 13) using declared catches of OEO from OEO 6 (Table 2 in the “Fishery summary” section of the Oreos report above) and tow-by-tow records of catch from the assessment area (Figure 8). The catch history used in the assessment is given in Table 13.

Table 13: Catch history (t) of black oreo from the Pukaki Rise fishery assessment area.

Year	Catch	Year	Catch	Year	Catch
1978–79	17	1990–91	15	2002–03	1 701
1979–80	5	1991–92	27	2003–04	1 530
1980–81	283	1992–93	27	2004–05	1 588
1981–82	4 180	1993–94	10	2005–06	2 811
1982–83	1 084	1994–95	242	2006–07	3 434
1983–84	1 150	1995–96	1 352	2007–08	3 346
1984–85	1 704	1996–97	2 413	2008–09	2 818
1985–86	46	1997–98	2 244	2009–10	3 093
1986–87	0	1998–99	1 181	2010–11	1 641
1987–88	0	1999–00	1 061	2011–12	1 671
1988–89	0	2000–01	1 158		
1989–90	0	2001–02	988		

Length data

Black oreo length frequency data collected by SOP and ORMC observers are available from the last 16 years (Table 14). An analysis indicated that there was a trend in fish size across years (with smaller mean lengths in more recent years) and with depth (deeper fish being larger). The length data were considered to be representative of the fishery in terms of the spatial, depth, and temporal coverage for those years that had adequate data. The length data were stratified into two depth bins: shallow (less than 900 m), and deep (greater than 900 m). Length data from adjacent years were grouped because of the low number of samples in some years (Figure 9). There is no trend in mean length over the first six year-groups, but fish sizes appear to be generally smaller in the later year-groups, with the mode of the distributions shifting to the left between 2005–06 and 2007–08.

Table 14: Summary of length frequency data for black oreo available from the assessment area. The table shows the number of tows sampled by year, the sample source, and the year group.

Year	Year group	Number of tows sampled		
		SOP	ORMC	All
1996-97	97-98	7	0	7
1997-98	97-98	25	0	25

Total		477	134	611

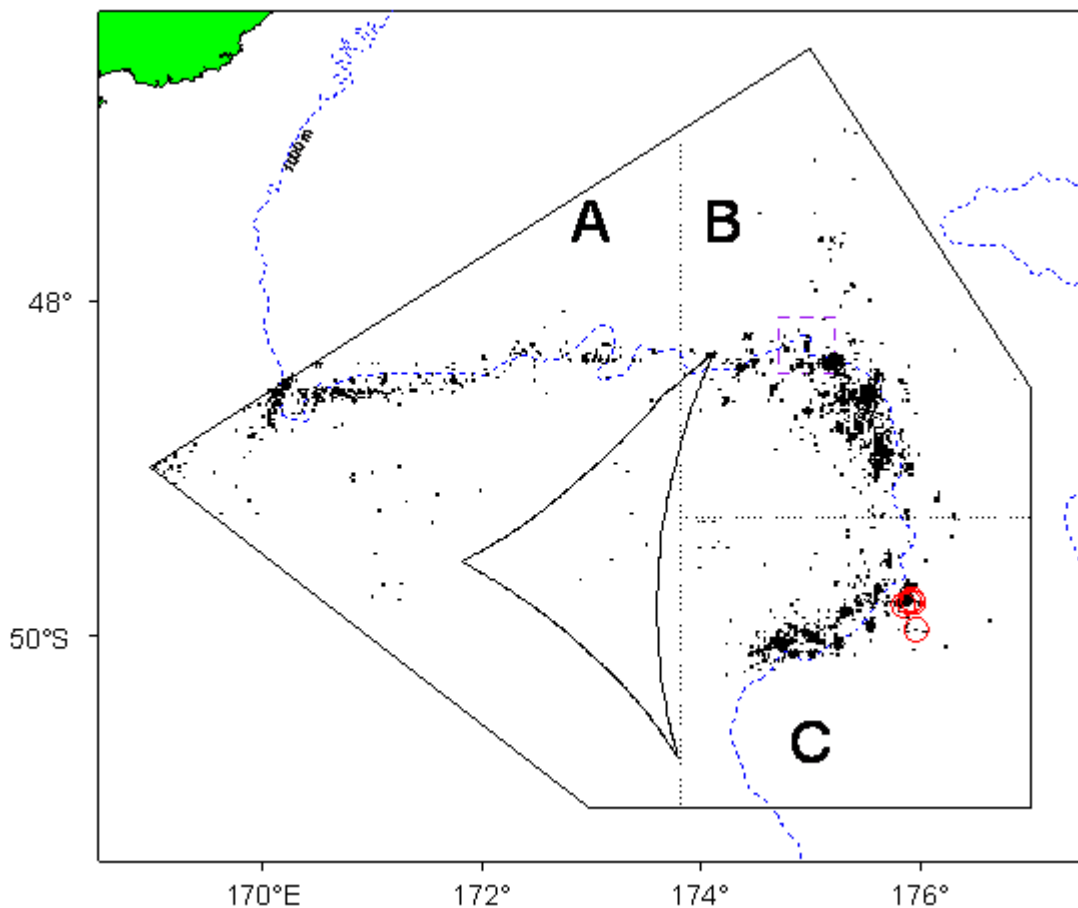

Figure 8: The Pukaki Rise fishery black oreo assessment area (polygon) abutting the boundary of OEO 6/OEO 1 in the north-west. The dots show tow positions where black oreo catch was reported between 1980-81 and 2011-12. A, B, and C are the three areas defined in the standardised CPUE analysis.

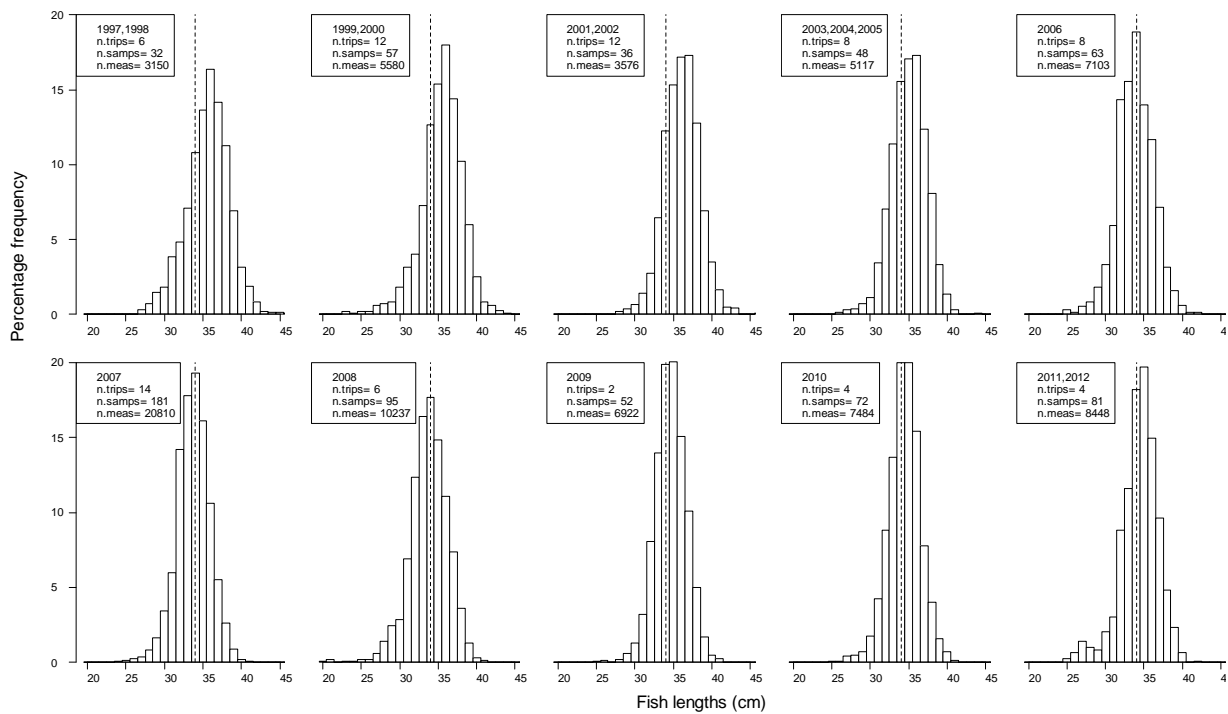

Figure 9: Observer length frequencies for Pukaki Rise black oreo, stratified by depth (see text), and grouped by years (in the legends 1997=1996–97 etc.). The vertical dashed lines indicate the approximate overall mean length as an aid to comparing the distributions.

Catch and effort data

The fishery taking Pukaki Rise black oreo divides into two distinct periods: a pre-GPS period 1980–81 to 1984–85 when much of the catch was taken by Soviet and Korean vessels, and a post-GPS period, 1995–96 to 2011–12 when most of the catch was taken by New Zealand vessels. The intervening period was characterised by low catches and the introduction of GPS technology in the fleet. Standardisation of CPUE for the pre-GPS period was attempted but rejected due to poor linkage of vessels across years and the shifting of fishing effort between areas. For the post-GPS period, the Working Group rejected CPUE as an index of abundance because of the variability in recorded target species over time and space in the overlapping Pukaki fisheries for black oreo, smooth oreo, and orange roughy. The Working Group believed that recording of target species in these fisheries was likely to have been inconsistent between vessels and skippers over time and that the practice of separately examining these fisheries according to recorded target species was inappropriate. Unstandardised catch and effort data for defined core vessels are presented in Table 15.

Table 15: Catch and effort data for vessels fishing in the eastern areas (B and C in Figure 8) with a minimum of 15 successful tows for black oreo in at least three years from 1995–96 to 2011–12.

Year	No. of tows	CPUE index	CV	Year	No. of tows	CPUE index	CV
1995–96	63	1.94	0.09	2004–05	309	0.73	0.13

4.5.2 Biomass estimates

No biomass estimates are reported.

OREOS (OEO 1&6)

4.5.3 Yield estimates and projections

No yield estimates were made.

No projections were made because the assessment was not accepted by the Working Group.

4.6 Other oreo fisheries in OEO 1 and OEO 6

4.6.1 Estimates of fishery parameters and abundance

Relative abundance estimates from trawl surveys

Two comparable trawl surveys were carried out in the Puysegur area of OEO 1 (TAN9208 and TAN9409). The 1994 oreo abundance estimates are markedly lower than the 1992 values (Table 16).

4.6.2 Biomass estimates

Estimates of virgin and current biomass are not yet available.

4.6.3 Yield estimates and projections

MCY cannot be estimated because of the lack of current biomass estimates for the other stocks.

CAY cannot be estimated because of the lack of current biomass estimates for the other stocks.

4.6.4 Other factors

Recent catch data from this fishery may be of poor quality because of area misreporting.

Table 16: OEO 1. Research survey abundance estimates (t) for oreos from the Puysegur and Snares areas. N is the number of stations. Estimates for smooth oreo were made based on a recruited length of 34 cm TL. Estimates for black oreo were made using knife-edge recruitment set at 27 cm TL.

<u>Smooth oreo</u>

1992	3 983	0	8 211	53	8
1994	1 564	0	3 566	64	7

5. STATUS OF THE STOCKS

Stock Structure Assumptions

Oreos in the OEO 1 and 6 FMAs are managed as a single stock but assessed as four separate stocks, separated by species and geography.

The Southland smooth oreo stock is based along the east coast of the South Island in OEO 1 but extends slightly into OEO 3. It does not include the Waitaki and Eastern canyon areas but is likely to have some level of mixing with other smooth oreo fishstocks. The Pukaki Rise smooth oreo stock comprises the major part of OEO 6 stocks and is centered on its namesake. Some mixing with other smooth oreo fishstocks is thought to occur. The Bounty Plateau smooth oreo stock is located across the Bounty Plateau and the Bounty Islands. Some mixing is thought to occur with other smooth oreo fishstocks.

The Pukaki Rise black oreo stock is the main black oreo fishstock in OEO 6 and the largest black oreo fishstock in the New Zealand EEZ. It extends the entire length of the Rise towards OEO 1. It is assessed separately to other fishstocks but managed as a part of OEO 6. Black oreo on the Pukaki Rise are thought to be non-mixing with other black oreo fishstocks.

• **OEO 1 and OEO 3A Southland (Smooth Oreo)**

Stock Status	
Year of Most Recent Assessment	2007
Assessment Runs Presented	One base case only
Reference Points	Target: 40% B_0 Soft Limit: 20% B_0 Hard Limit: 10% B_0
Status in relation to Target	B_{2007} was estimated at 27% B_0 , Unlikely (< 40%) to be at or above the target.
Status in relation to Limits	B_{2007} was estimated to be Unlikely (< 40%) to be below the Soft Limit and Very Unlikely (< 10%) to be below the Hard Limit.

Historical Stock Status Trajectory and Current Status

Predicted biomass trajectories for the 2007 base case assessment— mature biomass and selected biomass for the shallow and deep fisheries. Also shown are the CPUE indices from the pre- and post-GPS analysis for the deep fishery (in gray) and the post-GPS analyses for the shallow fishery (in black). CPUE indices are shown with +/- 2 s.e. confidence interval indicated by the vertical lines (the post-GPS CPUE data are slightly offset to avoid over plotting). The CPUE data were scaled by catchability coefficients to match the biomass scale.

Fishery and Stock Trends	
Recent Trend in Biomass or Proxy	Biomass has been declining at a steady rate since the late 1980s.
Recent Trend in Fishing Mortality or Proxy	Unknown
Other Abundance Indices	-
Trends in Other Relevant Indicators or Variables	-

OREOS (OEO 1&6)

Projections and Prognosis	
Stock Projections or Prognosis	None because of assessment uncertainty.
Probability of Current Catch or TACC causing decline below Limits	Soft Limit: Unknown Hard Limit: Unknown

Assessment Methodology	
Assessment Type	Type 1 - Quantitative Stock Assessment
Assessment Method	Age-structured CASAL model with Bayesian estimation of posterior distributions.
Main data inputs	- Length-frequency data collected by SOP and ORMC observers - A second, earlier fishery based on Soviet vessels was included in the assessment using historical catch data. - Standardised CPUE indices were derived from the historical and modern datasets.
Period of Assessment	Latest assessment: 2007 Next assessment: 2012
Changes to Model Structure and Assumptions	-
Major Sources of Uncertainty	- Scarcity of observer length frequency data - Poor quality area catch data due to significant misreporting - Lack of fishery-independent abundance estimates creates reliance on commercial CPUE data.

Qualifying Comments
-

Fishery Interactions
Both species of oreo are sometimes taken as bycatch in orange roughy target fisheries and in smaller numbers in hoki target fisheries. Target fisheries for oreos do exist, with main bycatch being orange roughy, rattails and deepwater sharks. Bycatch species of concern include deepwater sharks and rays, seabirds and deepwater corals.

Year of Most Recent Assessment	2013
Assessment Runs Presented	CASAL assessment based on CPUE rejected
Reference Points	Target: 40% B_0 Soft Limit: 20% B_0 Hard Limit: 10% B_0 Overfishing threshold: $F_{40\% B_0}$
Status in relation to Target	Unknown
Status in relation to Limits	Unknown
Status in relation to Overfishing	Unknown
Historical Stock Status Trajectory and Current Status	
-	

Fishery and Stock Trends	
Recent Trend in Biomass or Proxy	Biomass is likely to have been declining since 1996.
Recent Trend in Fishing Intensity or Proxy	Unknown
Other Abundance Indices	CPUE has steadily declined.
Trends in Other Relevant Indicators or Variables	-

Projections and Prognosis	
Stock Projections or Prognosis	No projections were made due to the uncertainties in the assessment.
Probability of Current Catch or TACC causing Biomass to remain below or to decline below Limits	Soft Limit: Unknown Hard Limit: Unknown
Probability of Current Catch or TACC causing Overfishing to continue or to commence	Unknown

Assessment Methodology and Evaluation	
Assessment Type	Type 1 - Quantitative Stock Assessment, but rejected.
Assessment Method	CASAL assessment based on CPUE (rejected)
Assessment Dates	Latest assessment: 2013 Next assessment: Unknown
Overall assessment quality rank	3 – Low Quality
Main data inputs (rank)	-
Data not used (rank)	Commercial CPUE 3 – Low Quality: does not track stock biomass
Changes to Model Structure and Assumptions	-
Major Sources of Uncertainty	- Lack of fishery-independent biomass estimates creates reliance on commercial CPUE data. - Lack of biological parameters specific to Smooth Oreo in the target area - data from Chatham Rise/Puysegur Bank had to be substituted instead.

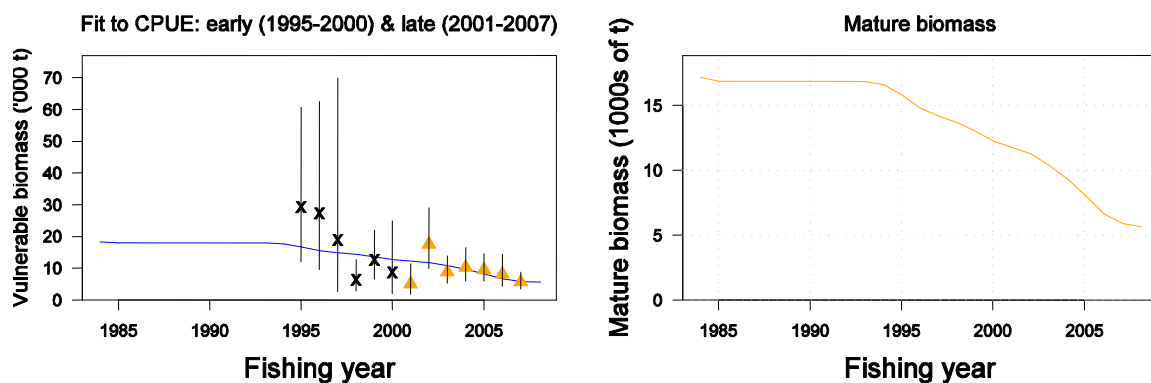

Qualifying Comments	
Further investigations into CPUE are required.	

Fishery Interactions	
Both species of oreo are sometimes taken as bycatch in orange roughy target fisheries and in smaller numbers in hoki target fisheries. Target fisheries for oreos do exist, with main bycatch being orange roughy, rattails and deepwater sharks. Low productivity bycatch species include deepwater sharks and rays. Protected species interactions occur with seabirds and deepwater corals.	

- **OEO 6 Bounty Plateau (Smooth Oreo)**

Stock Status	
Year of Most Recent Assessment	2008
Assessment Runs Presented	A base case with two sensitivity runs
Reference Points	Target: 40% B_0 Soft Limit: 20% B_0 Hard Limit: 10% B_0
Status in relation to Targe	B_{2008} was estimated at 33% B_0 ; Unlikely (< 40%) to be at or above the target.
Status in relation to Limits	B_{2008} is Unlikely (< 40%) to be below the Soft Limit and Very Unlikely (< 10%) to be below the Hard Limit.

Historical Stock Status Trajectory and Current Status

Model run showing the MPD fit to the CPUE data (vertical lines are the 95% confidence intervals for the indices) and the trajectory of mature biomass.

Fishery and Stock Trends

Recent Trend in Biomass or Proxy	Biomass is estimated to have been decreasing rapidly since 1995.
Recent Trend in Fishing Mortality or Proxy	Unknown
Other Abundance Indices	-
Trends in Other Relevant Indicators or Variables	-

Projections and Prognosis

Stock Projections or Prognosis	No projections were made because of the uncertainty of the assessment.
Probability of Current Catch or TACC causing decline below Limits	Soft Limit: Unknown Hard Limit: Unknown

Assessment Methodology

Assessment Type	Type 1 - Quantitative Stock Assessment	
Assessment Method	Age-structured CASAL model with Bayesian estimation of posterior distributions	
Main data inputs	<ul style="list-style-type: none"> - Catch history - Abundance estimates derived from a standardised CPUE - Length data from SOP and ORMC observers 	
Period of Assessment	Latest assessment: 2008	Next assessment: Unknown
Changes to Model Structure and Assumptions	-	
Major Sources of Uncertainty	<ul style="list-style-type: none"> - Reliance on commercial CPUE data - To estimate biological parameters, data was used from different stocks (Puysegur Bank + Chatham Rise) to the target stock - Using a single CPUE index instead of split indices gives contrasting biomass signals 	

Qualifying Comments

-

Fishery Interactions

Both species of oreo are sometimes taken as bycatch in orange roughy target fisheries and in smaller numbers in hoki target fisheries. Target fisheries for oreos do exist, with main bycatch being orange roughy, rattails and deepwater sharks. Bycatch species of concern include deepwater sharks and rays, seabirds and deepwater corals.

1. FISHERY SUMMARY

1.1 Commercial fisheries

Paddlecrabs were introduced into the QMS from 1 October 2002 with recreational and customary non-commercial allowances, TACCs and TACs summarised in Table 1.

Table 1: Recreational and Customary non-commercial allowances, TACCs and TACs for paddle crabs, by Fishstock.

Fishstock	Recreational Allowance	Customary non-Commercial Allowance	TACC	TAC
PAD 1	20	10	220	250
PAD 2	10	5	110	125
PAD 3	8	2	100	110
PAD 4	4	1	25	30
PAD 5	4	1	50	55
PAD 6	0	0	0	0

PAD 8	4	1	60	65
PAD 9	20	10	100	130
PAD 10	0	0	0	0

Commercial interest in paddle crabs was first realised in New Zealand in 1977–78 when good numbers of large crabs were caught off Westshore Beach, Napier in baited lift and set-pots. Annual catches have varied, mainly due to marketing problems, and estimates are likely to be conservative. Landings increased in the early fishery, from 775 kg in 1977 to 306 t in 1985, and 403 t in 1995–96 but have since generally decreased to a total of 121 t in 2011–12. Paddle crabs are known to be discarded from inshore trawl operations targeting species such as flatfish, and this may have resulted in under-reporting of catches. Crabs are marketed live, as whole cooked crabs, or as crab meat. Attempts were made to establish a soft-shelled crab industry in New Zealand in the late 1980s.

Bycatch is commonly taken during trawl, dredge and setnetting operations. Catch rates vary considerably with method, season and area, and there is no clear seasonal trend to paddle crab landings. It is likely that catches are related to the availability of fishers and/or market demands. Commercial landings from 1989–90 until the present are shown in Table 2, while Figure 1 shows the historical landings and TACC for the six main PAD stocks.

PADDLE CRABS (PAD)

1.2 Recreational fisheries

Indicative data from the 1996 National Marine Recreational Fishing Survey show that paddle crabs are seldom caught by recreational fishers (NIWA unpublished). Paddle crabs are taken as a bycatch of beach and estuarine seining and in setnets throughout much of their geographical range.

1.3 Customary non-commercial fisheries

There is no quantitative information on the current level of customary non-commercial catch.

1.4 Illegal catch

There is no quantitative information available on the current level of illegal catch.

1.5 Other sources of mortality

There is no quantitative information available on other sources of mortality, although unknown quantities of paddle crabs have been discarded from commercial fishing operations such as the inshore trawl, setnet and dredge fisheries.

2. BIOLOGY

The paddle crab is found off sandy beaches, and in harbours and estuaries throughout mainland New Zealand, the Chatham Islands, and east and south Australia. They are abundant from the intertidal zone to at least 10 m depth, although they do occur in much deeper water. Paddle crabs are mainly active in early evening or at night, when they move into the shallow intertidal zone to feed.

Paddle crabs are versatile and opportunistic predators. They feed mainly on either molluscs or crustaceans, but also on polychaetes, several fish species, cumaceans, and occasionally on algae. A high proportion of the molluscs eaten are *Paphies* species. These include: tuatua (*P. subtriangulata*); pipi (*P. australis*); and toheroa (*P. ventricosa*). The burrowing ghost shrimp *Callinassa filholi*, isopods and amphipods are important crustacean prey items. Cannibalism is common, particularly on small crabs and during the winter moulting season.

Anecdotal information suggests there has been a significant increase in paddle crab numbers since the 1970s. Concern has been expressed as to the impact of an increased number of paddle crabs on bivalve shellfish stocks in coastal waters. Feeding studies have shown that although paddle crabs do eat large adult toheroa and other shellfish, they more usually eat bivalve shellfish spat which are found in abundance.

Mating generally occurs during winter and spring (May to November) in sheltered inshore waters. Female paddle crabs can only mate when they are soft-shelled. Male crabs protect and carry pre-moult females to ensure copulation. Female crabs are thought to migrate to deeper water to spawn over the warmer months (September to March). After spawning the eggs are incubated until they hatch. *Ovalipes catharus* has an extended larval life characterised by eight zoea stages and a (crab-like) megalopa. The larvae are thought to live offshore in deeper water, migrating inshore in the megalopa stage to settle from January to May.

Two spawning mechanisms have been observed in *O. catharus*. In Wellington, Tasman Bay, and Canterbury, spawning does not appear to be synchronised and females may spawn several times during the season (non-synchronous spawning). In Blueskin Bay, Otago, paddle crabs are group-synchronous, with one clutch of eggs developing to maturity over winter, and spawned from September to February.

Annual fecundity is determined by the number of eggs per brood (brood fecundity) and the number of broods per year. Both these parameters are size dependent and highly variable. Brood fecundity estimates vary considerably geographically from between 82 000–638 000 in Wellington waters, to 100 000–1 200 000 in Canterbury waters, and 931 000–2 122 807 in Otago waters. The number of broods per year also varies geographically from 1.2–3.3 in Wellington waters, to 1.2–2.2 in Canterbury waters, and 1 brood per year in Otago waters (group synchronous spawning).

O. catharus is a relatively large and fast growing species of *Ovalipes*. In Canterbury waters, paddle crabs reach a maximum size of 130 mm carapace width (CW - males only) after 13 postlarval moults and 3 to 4 years after settlement. Other studies have reported maximum sizes up to 150 mm CW. In Wellington waters, crabs of approximately 100 mm carapace width, of either sex, would be at least 3 years old, while larger crabs could be 4 or 5 years old.

The differences in growth rate, size at first maturity, and fecundity (particularly the number of broods) appear to be largely environmentally regulated. At lower temperatures and higher latitudes, paddle crabs grow slower, mature at a larger size, have a shorter breeding season, and produce fewer broods per year.

Estimates of biological parameters relevant to stock assessment are presented in Table 3.

Table 3: Estimates of biological parameters.

Fishstock	Estimate		Source	
<u>1. Natural mortality (females only)</u>				
(Percentage mortality at each instar stage)

	a	b		a
	-3.32	2.79	-3.46	2.89
				Davidson & Marsden (1987)

3. STOCKS AND AREAS

It is not known whether biologically distinct stocks occur, although this seems unlikely given that the species is found throughout New Zealand waters, and from tagging experiments, appears to be highly migratory. There is probably also widespread larval dispersal as larvae spend two months offshore in deeper water (to at least 700 m). Genetically distinct populations may occur in isolated areas such as the Chatham Islands.

4. STOCK ASSESSMENT

4.1 Estimates of fishery parameters and abundance

None are available at present.

4.2 Biomass estimates

No estimates of current or virgin biomass are available. The landings, CPUE, and area data are considered too unreliable or incomplete to allow modelling.

4.3 Yield estimates and projections

MCY cannot be estimated.

CAY cannot be estimated because of the lack of current biomass estimates.

5. STATUS OF THE STOCKS

Estimates of current and reference biomass are not available. Landings have fluctuated significantly in most QMAs, mainly due to market variations. Paddle crabs are abundant throughout most of their range and the fishery is probably only lightly exploited.

PARORE (PAR)*(Girella tricuspidata)*

Parore

**1. FISHERY SUMMARY**

Parore was introduced into the Quota Management System (QMS) on 1 October 2004 with the TACs, TACCs and allowances shown in Table 1.

Table 1: TACs (t), TACCs (t) and allowances (t) for parore.

Fishstock	Recreational Allowance	Customary non-commercial Allowance	Other sources of mortality	TACC	TAC
PAR 1	6	3	4	61	74
PAR 2	1	1	0	2	4
PAR 9	2	1	1	21	25
PAR 10	0	0	0	0	0
Total	9	5	5	84	103

1.1 Commercial fisheries

Parore is principally caught as a bycatch in the grey mullet, flatfish and trevally setnet fisheries in northern New Zealand. Most of the catch comes from eastern Northland and the Firth of Thames (FMA 1) and the Kaipara and Manukau Harbours (FMA 9) (Figure 1). Highest catch rates occur during September to October. Few parore are caught in the other FMAs. Reported landings and TACCs for Parore are given in Tables 2 and 3.

Fishers may confuse the codes PAR (parore) and POR (porae) when reporting catches, but given that both species occur in shallow northern waters, misreporting is difficult to discern.

Table 2: Reported landings (t) of parore by FMA, fishing years 1989–90 to 2003–04. [Continued on next page].

	FMA 1	FMA 2	FMA 3	FMA 4	FMA 5	FMA 7	FMA 8	FMA 9

1.2 Recreational fisheries

The National Marine Recreational Fishing surveys in 1994, 1996, and 2000 do not provide estimates of recreational catches of parore. There is likely to be some recreational catch in northern areas as a bycatch when targeting other species such as snapper, trevally, and mullet. These catches are most likely taken by setnetting, as well as being targeted opportunistically by spear fishing. Parore is considered to be a low value recreational species and current catches are likely to be low.

Non-commercial catches are likely to increase in the future as a result of the increasing human population in northern New Zealand, and the likely increase in the number of recreational fishers. Increased targeting may also occur as parore are considered good eating.

1.3 Customary non-commercial fisheries

There is no quantitative information on customary harvest levels of parore. Customary fishers are likely to catch small quantities of parore when targeting other species such as snapper, trevally, and mullet. Parore is considered to be a low value customary species and current catches are likely to be low.

2. BIOLOGY

Parore (*Girella tricuspidata*) occur along both east and west coasts of the North Island, from North Cape to Cook Strait (Anderson et al 1998). It has not been recorded around the Chatham Islands. They usually occur in schools, ranging from half a dozen to several hundred individuals. Although there is evidence that large individuals display territorial behaviour on some reef systems, work in Australia has shown that parore are capable of moving distances of hundreds of kilometres (Pollock 1981).

Parore grow to a maximum size of at least 600 mm, but most adult fish are around 300–400 mm in length. The maximum age for this species on the North Island east coast, as estimated by scale ring counts (validated by seasonal increments), is 10 years (Morrison 1990). As scales tend to provide underestimates of the age of older fish, maximum age could be considerably higher. Growth is relatively rapid in the first year of life, with fish reaching a size of about 100 mm at age one. Fish reach a length of 300 mm by age five, at which time growth slows. Growth rates of males and females, and of open coast and estuarine populations, appear similar. No growth studies have been undertaken on the west coast of the North Island, but large parore (about 600 mm) are sometimes taken in harbour set-nets as bycatch.

Parore reach sexual maturity at a length of 280 mm and spawning takes place in late spring to early summer (Morrison 1990). Larvae are neustonic, occurring near the ocean's surface, often in association with drifting material such as seaweed clumps.

Juveniles enter estuaries in January at a length of about 11 mm. They are initially found on seagrass meadows and beds of Neptune's Necklace (*Hormosira banksii*) on shallow reefs, but after 3–4 months move down the estuary to other habitats e.g., brown kelp beds. At approximately one year old, they move out to coastal reefs in the immediate vicinity of estuary mouths and over the following 2–3 years move to reef systems further off- and along-shore (Morrison 1990).

Parore are important herbivores in coastal systems and may play a significant role in structuring algal assemblages (Morrison 1990). Juvenile parore have been found in the stomachs of kahawai and John dory.

There is no fishery independent information to determine the stock status of parore. Biomass estimates cannot be determined for this species with existing data.

3. STOCKS AND AREAS

There is insufficient biological information available on this species to indicate the existence of separate stocks around New Zealand. However, reliance on localized nursery areas suggests that more than one biological stock may exist.

4. STOCK ASSESSMENT

There has been no scientific assessment of the maximum sustainable yield for parore stocks.

5. STATUS OF THE STOCK

Estimates of current and reference biomass are not available. It is not known if recent catch levels or TACs are sustainable. The status of PAR 1, 2 and 9 relative to B_{MSY} is unknown.

TACCs and reported landings of parore by Fishstock, for the 2012–13 fishing year, are summarised in Table 4.

1. INTRODUCTION

Specific Working Group reports are given separately for PAU 2, PAU 3, PAU 4, PAU 5A, PAU 5B, PAU 5D and PAU 7. The TACC for PAU 1, PAU 6 and PAU 10 is 1.93 t, 1 t and 1 t respectively. Commercial landings for PAU 10 since 1983 have been 0 t.

1.1 Commercial fisheries

The commercial fishery for paua dates from the mid-1940s. In the early years of this commercial fishery the meat was generally discarded and only the shell was marketed, however by the late 1950s both meat and shell were being sold. Since the 1986–87 fishing season, the eight Quota Management Areas have been managed with an individual transferable quota system and a total allowable catch (TAC) that is made up of; total allowed commercial catch (TACC), recreational and customary catch and other sources of mortality.

Fishers gather paua by hand while free diving (use of underwater breathing apparatus is not permitted). Most of the catch is from the Wairarapa coast southwards: the major fishing areas are in the South Island, Marlborough (PAU 7), Stewart Island (PAU 5A, 5B and 5D) and the Chatham Islands (PAU 4). Virtually the entire commercial fishery is for the black-foot paua, *Haliotis iris*, with a minimum legal size for harvesting of 125 mm shell length. The yellow-foot paua, *H. australis* is less abundant than *H. iris* and is caught only in small quantities; it has a minimum legal size of 80 mm. Catch statistics include both *H. iris* and *H. australis*.

Up until the 2002 fishing year, catch was reported by general statistical areas, however from 2002 onwards, a more finely scaled system of paua specific statistical areas were put in place throughout each QMA (refer to the QMA specific Working Group reports). Figure 1 shows the historical landings for the main PAU stocks. On 1 October 1995 PAU 5 was divided into three separate QMAs: PAU 5A, PAU 5B and PAU 5D.

PAUA (PAU)

H experimental landings

* FSU data

1.2 Recreational fisheries

There is a large recreational fishery for paua. Estimated catches from telephone and diary surveys of recreational fishers (Teirney et al 1997, Bradford 1998, Boyd & Reilly 2004, Boyd et al 2004) are shown in Table 2. In 1996–97 sufficient diary data were available for an estimate in PAU 5D only (Bradford 1998, NIWA unpublished data). The Marine Recreational Fisheries Technical Working Group (RFTWG) has reviewed the harvest estimates from the national surveys. Due to a methodological error in the methodology, the harvest estimates for 1991–92 to 1993–94 and 1996–97 are not considered to be reliable. The harvest estimates for the 1999–2000 and 2000–01 surveys may be very inaccurate and some implausibly high. This may be due to a number of factors including the accuracy of the mean weight used to derive total harvest weight from the estimated numbers of paua caught by diarists, and the small number of diarists harvesting the stock in some areas. However relative comparisons can be made between stocks within the surveys.

Table 2: Estimated annual harvest of paua (t) by recreational fishers*.

Fishstock	PAU 1	PAU 2	PAU 3	PAU 5	PAU 5D	PAU 6	PAU 7

*1991–1995 Regional telephone/diary estimates, 1995/96, 1999/00 and 2000/01 National Marine Recreational Fishing Surveys.

1.3 Customary fisheries

There is an important customary use of paua by Maori for food, and the shells have been used extensively for decorations and fishing devices. Limited data is available for reported customary landings in PAU 3; however no information is available for current levels of customary take for any other paua QMA. Kaitiaki are now in place in many areas and estimates of customary harvest can be expected in the future.

1.4 Illegal catch

Current levels of illegal harvests are not known. In the past, annual estimates of illegal harvest for some Fishstocks were provided by MFish Compliance based on seizures. In the current paua stock assessments, nominal illegal catches are used.

1.5 Other sources of mortality

Paua may die from wounds caused by removal desiccation or osmotic and temperature stress if they are brought to the surface. Sub-legal paua may be subject to handling mortality by the fishery if they are removed from the substrate to be measured. Further mortality may result indirectly from being returned to unsuitable habitat or being lost to predators or bacterial infection. Gerring (2003) observed paua (from PAU 7) with a range of wounds in the laboratory and found that only a deep cut in the foot caused significant mortality (40% over 70 days). In the field this injury reduced the ability of paua to right themselves and clamp securely onto the reef, and consequently made them more vulnerable to predators. The tool generally used by divers in PAU 7 is a custom made stainless steel knife with a rounded tip and no sharp edges. This design makes cutting the paua very unlikely (although abrasions and shell damage may occur). Gerring (2003) estimated that in PAU 7, 37% of paua removed from the reef by commercial divers were undersize and were returned to the reef. His estimate of incidental mortality associated with fishing in PAU 7 was 0.3% of the landed catch. Incidental fishing mortality may be higher in areas where other types of tools and fishing practices are used. Mortality may increase if paua are kept out of the water for a prolonged period or returned onto sand. To date, the stock assessments developed for paua have assumed that there is no mortality associated with capture of undersize animals.

2. BIOLOGY

Paua are herbivores which can form large aggregations on reefs in shallow subtidal coastal habitats. Movement is over a sufficiently small spatial scale that the species may be considered sedentary. Paua are broadcast spawners and spawning is thought to be annual. Habitat related factors are an important source of variation in the post-settlement survival of paua. Growth, morphometrics, and recruitment can vary over short distances and may be influenced by factors such as wave exposure, habitat structure, availability of food and population density. A summary of generic estimates for biological parameters for paua are presented in Table 3. Parameters specific to individual paua QMAs are reported in the specific Working Group reports.

Table 3: Estimates of biological parameters for paua (*H. iris*).

Fishstock	Estimate	Source
<u>1. Natural mortality (<i>M</i>)</u>		
All	0.02–0.25	Sainsbury (1982)
<u>2. Weight = a (length)^b (weight in kg, shell length in mm)</u>		
	a = 2.99E ⁻⁰⁸	b = 3.303 Schiel & Breen (1991)

3. STOCKS AND AREAS

Using both mitochondrial and microsatellite markers Will & Gemmell (2008) found high levels of genetic variation within samples of *H. Iris* taken from 25 locations spread throughout New Zealand. They also found two patterns of weak but significant population genetic structure. Firstly, *H. iris* individuals collected from the Chatham Islands were found to be genetically distinct from those collected from coastal sites around the North and South Islands. Secondly a genetic discontinuity was found loosely associated with the Cook Strait region. Genetic discontinuities within the Cook Strait region have previously been identified in sea stars, mussels, limpets, and chitons and are possibly related to contemporary and/or past oceanographic and geological conditions of the region. This split may have some implications for management of the paua stocks, with populations on the south of the North Island, and the north of the South Island potentially warranting management as separate entities; a status they already receive under the zonation of the current fisheries regions, PAU 2 in the North Island, and PAU 7 on the South Island.

4. STOCK ASSESSMENT

The dates of the most recent survey or stock assessment for each QMA are listed in Table 4.

Table 4: Recent survey and stock assessment information for each paua QMA

QMA	Type of survey or assessment	Date	Comments
PAU 1	No surveys or assessments have been undertaken		
PAU 2	Relative abundance estimate using standardised CPUE index based on commercial catch	2007	Standardised CPUE increased between 1992 and 2000 and has remained fairly stable up to 2007.
PAU 3	Quantitative assessment using a Bayesian length based model	2013	For the 2013 stock assessment nine model runs were conducted. The Shellfish Working Group agreed on a base case model which estimated M within the model but fixed the growth parameters as providing a reliable estimate of the status of the stocks in PAU 3 with the caveat that the model most likely underestimated uncertainty in growth but adequately estimated uncertainty in natural mortality.
PAU 4	Quantitative assessment using a Bayesian length based model	2004	In February 2010 the Shellfish Working Group (SFWG) agreed that due to the lack of adequate data as input into the Bayesian length-based model, a stock assessment for PAU 4 using this model was not appropriate. Other performance indicators that could be used as reference points around which to assess the status of the stocks are being evaluated for use in PAU 4
PAU 5A	Quantitative assessment using a Bayesian length based model	2010	The 2010 stock assessment was conducted over two subareas of the QMA. The SFWG was satisfied that the stock assessment for both the Southern and Northern areas was reliable based on the available data. It was agreed by the SFWG that the range of estimated indicators for both the base case and hyperstability models used in the Northern area assessment were acceptable, but where within the range of estimates the actual status of the fishery is located is not clear.
PAU 5B	Quantitative assessment using a Bayesian length based model	2013	The SFWG were satisfied that the stock assessment provided a reliable estimate of the status of the stocks in PAU 5B. Sensitivity trials addressed uncertainties associated with various aspects of the input data and model assumptions.
PAU 5D	Quantitative assessment using a Bayesian length based model	2012	Four assessment runs were presented and all considered to be equally plausible. All runs showed that it was Very Unlikely the stock will fall below the soft or hard limits over the next three years at current levels of catch, and suggested that biomass would increase. However, the four runs differed in their assessment of the status of the stock relative to the target.
PAU 6	Biomass estimate	1996	This fishery has a TACC of 1 t
PAU 7	Quantitative assessment using a Bayesian length based model	2012	The SFWG agreed that the stock assessment was reliable based on the available data. Currently, spawning stock biomass is estimated at 22% B_0 . Results suggest an increase to 23.4% B_0 in over the next three years at current levels of catch.
PAU 10	No surveys or assessments have been undertaken		

4.1 Estimates of fishery parameters and abundance

For further information on fishery parameters and abundance specific to each paua QMA refer to the specific Working Group report.

In 2008 standardised CPUE indices were constructed to assess relative abundance in PAU 2. In QMAs where quantitative stock assessments have been undertaken, standardised CPUE is also used as input data for the Bayesian length-based stock assessment model. There is however a large amount of literature on abalone which suggests that any apparent stability in CPUE should be interpreted with caution and CPUE may not be proportional to abundance as it is possible to maintain high catch rates despite a falling biomass. This occurs because paua tend to aggregate and in order to maximise their catch rates divers' move from areas that have been depleted of paua, to areas with higher density. The consequence of this fishing behaviour is that overall abundance is decreasing while CPUE is remaining stable. This process of hyperstability is believed to be of less concern in PAU 3, PAU 5D and PAU 7 because fishing in these QMAs is consistent across all fishable areas.

In PAU 4, 5A, 5B, 5D and 7 the relative abundance of paua has also been estimated from independent research diver surveys (RDS). In PAU 7, seven surveys have been completed over a number of years but only two surveys have been conducted in PAU 4. In 2009 and 2010 several reviews were conducted (Cordue (2009) and Haist V (2010 MPI .FRR) to assess; i) the reliability of the research diver survey index as a proxy for abundance; and ii) whether the RDS data, when used in the paua stock assessment models, results in model outputs that do not adequately reflect the status of the stocks. The reviews concluded that:

- Due to inappropriate survey design the RDS data appear to be of very limited use for constructing relative abundance indices.
- There was clear non-linearity in the RDS index, the form of which is unclear and could be potentially complex.
- CVs of RDS index 'year' effects are likely to be underestimated, especially at low densities.
- Different abundance trends among strata reduces the reliability of RDS indices, and the CVs are likely not to be informative about this.
- It is unlikely that the assessment model can determine the true non-linearity of the RDS index-abundance relationship because of the high variability in the RDS indices.
- The non-linearity observed in the RDS indices is likely to be more extreme at low densities, so the RDSI is likely to mask trends when it is most critical to observe them.
- Existing RDS data is likely to be most useful at the research stratum level.

4.2 Biomass estimates

Biomass was estimated for PAU 6 in 1996 (McShane et al 1996). However the survey area was only from Kahurangi Point to the Heaphy River.

Biomass has been estimated, as part of the stock assessments, for PAU 4, 5A, 5B, 5D and 7 (Table 4). For further information on biomass estimates specific to each paua QMA refer to the specific Working Group report.

4.3 Yield Estimates and Projections

Yield estimates and projections are estimated as part of the stock assessment process. Both are available for PAU 5A, 5D and 7. For further information on yield estimates and projections specific to each paua QMA refer to the specific Working Group report.

4.4 Other factors

In the last few years the commercial fishery have been implementing voluntary management actions in the main QMAs. These management actions include raising the minimum harvest size and subdividing QMAs into smaller management areas and capping catch in the different areas

5. ENVIRONMENTAL AND ECOSYSTEM CONSIDERATIONS

5.1. Ecosystem role

Paua are eaten by a range of predators, and smaller paua are generally more vulnerable to predation. Smaller paua are consumed by blue cod (Carbines and Beentjes 2003), snapper (Francis 2003), banded wrasse (Russell 1983), spotties (McCardle 1983), triplefins (McCardle 1983) and octopus (Andrew & Naylor 2003). Large paua are generally well protected by their strong shells, but are still vulnerable to rock lobsters (McCardle 1983), the large predatory starfishes *Astrostele scabra* and *Coscinasterias muricata* (Andrew & Naylor 2003). Large paua are also vulnerable to predation by eagle rays (McCardle 1983), but Ayling & Cox (1982) suggested that eagle rays feed almost exclusively on Cook's turban. There are no known predators that feed exclusively on paua.

Paua feed preferentially on drift algae but at high densities they also feed by grazing attached algae. They are not generally considered to have a large structural impact upon algal communities but at high densities they may reduce the abundance of algae. There are no recognised interactions with paua abundance and the abundance or distribution of other species, with the exception of kina which, at very high densities, appear to exclude paua (Andrew et al 2000). Research at D'Urville Island and on Wellington's south coast suggests that there is some negative association between paua and kina (Andrew & MacDiarmid 1999).

5.2. Fish and invertebrate bycatch

Because paua are harvested by hand gathering, incidental bycatch is limited to epibionts attached to, or within the shell. The most common epibiont on paua shell is non-geniculate coralline algae, which, along with most other plants and animals which settle and grow on the shell, such as barnacles, oysters, sponges, bryozoans, and algae, appears to have general habitat requirements (i.e. these organisms are not restricted to the shells of paua). Several boring and spiral-shelled polychaete worms are commonly found in and on the shells of paua. Most of these are found on several shellfish species, although within New Zealand's shellfish, the onuphid polychaete *Brevibrachium maculatum* has been found only in paua shell Handley, S. (2004). This species; however, has been reported to burrow into limestone, or attach its tube to the holdfasts of algae (Read 2004). It is also not uncommon for paua harvesters to collect predators of paua (mainly large predatory starfish) while fishing and to effectively remove these from the ecosystem. The levels of these removals are unlikely to have a significant effect on starfish populations (nor, in fact, on the mortality of paua caused by predation).

5.3. Incidental catch (seabirds, mammals, and protected fish)

There is no known bycatch of threatened, endangered, or protected species associated with the hand gathering of paua.

5.4. Benthic interactions

The environmental impact of paua harvesting is likely to be minimal because paua are selectively hand gathered by free divers. Habitat contact by divers at the time of harvest is limited to the area of paua foot attachment, and paua are usually removed with a blunt tool to minimise damage to the flesh. The diver's body is also seldom in full contact with the benthos. Vessels anchoring during or after fishing have the potential to cause damage to the reef depending on the type of diving operation (in many cases, vessels do not anchor during fishing). Damage from anchoring is likely to be greater in areas with fragile species such as corals than it is on shallow temperate rocky reefs. Corals are relatively abundant at shallow depths within Fiordland, but there are seven areas within the sounds with significant populations of fragile species where anchoring is prohibited.

5.5. Other considerations

5.5.1 Genetic effects

Fishing, environmental changes, including those caused by climate change or pollution, could alter the genetic composition or diversity of a species and there is some evidence to suggest that genetic changes may occur in response to fishing of abalones. Miller et al (2009) suggested that, in *Haliotis rubra* in Tasmania, localised depletion will lead to reduced local reproductive output which may, in

turn, lead to an increase in genetic diversity because migrant larval recruitment will contribute more to total larval recruitment. Enhancement of paua stocks with artificially-reared juveniles has the potential to lead to genetic effects if inappropriate broodstocks are used.

5.5.2 Biosecurity issues

Undaria pinnatifida is a highly invasive opportunistic kelp which spreads mainly via fouling on boat hulls. It can form dense stands underwater, potentially resulting in competition for light and space which may lead to the exclusion or displacement of native plant and animal species. *Undaria* may be transported on the hulls of paua dive tenders to unaffected areas. Bluff Harbour, for example, supports a large population of *Undaria*, and is one of the main ports of departure for fishing vessels harvesting paua in Fiordland, which appears to be devoid of *Undaria* (R. Naylor, personal observation). In 2010, a small population of *Undaria* was found in Sunday Cove in Breaksea Sound, and attempts to eradicate it appear to have been successful (see <http://www.biosecurity.govt.nz/pests/undaria>).

6. STATUS OF THE STOCKS

The status of paua stocks PAU 2, PAU 3, PAU 4, PAU 5A, PAU 5B, PAU 5D and PAU 7 are given in the relevant Working Group reports.

PAUA (PAU 2) – Wairarapa / Wellington / Taranaki

(Haliotis iris)
Paua

**1. FISHERY SUMMARY**

PAU 2 was introduced into the Quota Management System in 1986–87 with a TACC of 100 t. As a result of appeals to the Quota Appeal Authority, the TACC was increased to 121.19 t in 1989 and has remained unchanged to the current fishing year (Table 1). There is no TAC for this QMA: before the Fisheries Act (1996) a TAC was not required. When changes have been made to a TACC after 1996, stocks have been assigned a TAC.

Table 1: Total allowable catches (TAC, t) allowances for customary fishing, recreational fishing, and other sources of mortality (t) and Total Allowable Commercial Catches (TACC, t) declared for PAU 2 since introduction to the QMS.

Year	TAC	Customary	Recreational	Other mortality	TACC
1986–1989	-	-	-	-	100
1989–present	-	-	-	-	121.19

1.1 Commercial fisheries

The fishing year runs from 1 October through to 30 September. Most of the commercial catch comes from the Wairarapa and Wellington South coasts between Castle Point and Turakirae Head. The western area between Turakirae Head and the Waikanae River is closed to commercial fishing.

On 1 October 2001 it became mandatory to report catch and effort on PCELRs using the fine-scale reporting areas that had been developed by the New Zealand Paua Management Company for their voluntary logbook programme (Figure 1).

1.2 Recreational fisheries

For further information on recreational fisheries refer to the introductory PAU Working Group Report.

Because paua around Taranaki are naturally small and never reach the minimum legal size (MLS) of 125 mm, a new MLS of 85 mm was introduced for recreational fishers from 1 October 2009. The new length is on a trial basis for five years and applies between the Awakino and Wanganui rivers.

Figure 1: Map of fine scale statistical reporting areas for PAU 2.

Landings for PAU 2 are shown in Table 2.

Table 2: TACC and reported landings (t) of paua in PAU 2 from 1983–84 to present.

Year	Landings	TACC
1983–84*	110	–
1984–85*	154	–
1985–86*	92	–
1986–87*	96.2	100
1987–88*	122.11	111.33
1988–89*	121.5	120.12
1989–90	127.28	121.19
1990–91	125.82	121.19
1991–92	116.66	121.19

2012–13	122	121

* FSU data.

1.3 Customary fisheries

For further information on customary fisheries refer to the introductory PAU Working Group Report.

1.4 Illegal catch

It is widely believed that the level of illegal harvesting is high around Wellington and on the Wairarapa coast. For further information on illegal catch refer to the introductory PAU Working Group Report.

Figure 2: Historical landings and TACC for PAU 2 from 1983–84 to present. QMS data from 1986–present.

1.5 Other sources of mortality

For further information on other sources of mortality refer to the introductory PAU Working Group Report.

2. BIOLOGY

For further information on paua biology refer to the introductory PAU Working Group Report. A summary of published estimates of biological parameters for PAU 2 is presented in Table 3.

Table 3: Estimates of biological parameters (*H. iris*)

Area		Estimate	Source
<u>1. Size at maturity (shell length)</u>			
Wellington	50% mature	71.7 mm	Naylor et al. (2006)
Taranaki	50% mature	58.9 mm	Naylor & Andrew (2000)
<u>2. Fecundity = a (length)^b (eggs, shell length in mm)</u>			
Taranaki	a = 43.98	b = 2.07	Naylor & Andrew (2000)
<u>3. Exponential growth parameters (both sexes combined)</u>			
Wellington	g ₅₀	30.58 mm	Naylor et al. (2006)
	g ₁₀₀	14.8 mm	
Taranaki	G ₂₅	18.4 mm	Naylor & Andrew (2000)
	G ₇₅	2.8 mm	

3. STOCKS AND AREAS

For further information on stocks and areas refer to the introductory PAU Working Group Report.

4. RELATIVE ABUNDANCE INDEX

A standardised CPUE index based on commercial catch was constructed covering the 1990 to 2007 fishing years (McKenzie et al 2009). The index was based on CELR data for 1990 to 2001, and PCELR data collapsed into CELR format for 2002 to 2007, with units of kilograms per diver day. The index shows a decline from 1990 to 1992, increasing to 2000, then fluctuating but essentially constant since (Table 4, Figure 3). A large portion of PAU 2, including the Wellington south coast, is closed to commercial fishing. This means that the CPUE series collected from the commercial catch and effort

data are exclusive of this large area. Given that it is widely believed that the level of illegal harvesting is high around Wellington, the abundance of paua in the fishery as a whole will not be captured very well by the CPUE index, which will only reflect abundance outside of the closed area. This is a cause for concern if stocks in the closed area are being depleted.

There is also a large amount of literature on abalone which suggests that any apparent stability in CPUE should be interpreted with caution; and CPUE may not be proportional to abundance as it is possible to maintain high catch rates despite a falling biomass. This occurs because paua tend to aggregate and in order to maximise their catch rates divers' move from areas that have been depleted of paua, to areas with higher density. The consequence of this fishing behaviour is that overall abundance is decreasing but CPUE is remaining stable.

Table 4: The standardised CPUE for PAU 2, 1990–2007.

Fishing year	Number of records	Standardised CPUE	CV
1990	288	111	0.11
1991	413	91	0.10
1992	320	86	0.10
1993	286	96	0.11
1994	253	92	0.10
1995	220	107	0.11
1996	230	108	0.11
1997	228	111	0.11
1998	141	139	0.12
1999	191	155	0.12
2000	188	162	0.12
2001	180	138	0.12
2002	140	149	0.12
2003	153	157	0.12
2004	148	166	0.12
2005	148	147	0.12
2006	166	156	0.12
2007	166	147	0.12

PAUA (PAU 3) – Canterbury / Kaikoura

(*Haliotis iris*)
Paua

1. FISHERY SUMMARY

1.1 Commercial fisheries

PAU 3 was introduced into the Quota Management System in 1986–87 with a TACC of 57 t. As a result of appeals to the Quota Appeal Authority, the TACC was increased to 91.62 t in 1995 and has remained unchanged to the current fishing year (Table 1).

There is no TAC for PAU 3 (Table 1): before the Fisheries Act (1996) a TAC was not required. When changes have been made to a TACC after 1996, stocks have been assigned a TAC. No allowances have been made for customary, recreational or other mortality.

Table 1: Total allowable catches (TAC, t) allowances for customary fishing, recreational fishing, and other sources of mortality (t) and Total Allowable Commercial Catches (TACC, t) declared for PAU 3 since introduction to the QMS.

Year	TAC	Customary	Recreational	Other mortality	TACC
1986–1995	-	-	-	-	57
1995–present	-	-	-	-	91.615

The fishing year runs from 1 October through 30 September.

Most of the commercial catch comes from the northern part of the QMA between the northern end of Pegasus Bay and the Clarence River, and from the southern side of Banks Peninsula.

On 1 October 2001 it became mandatory to report catch and effort on Paua Catch Effort Landing Returns (PCELRs) using fine-scale reporting areas that had been developed by the New Zealand Paua Management Company for their voluntary logbook programme (Figure 1). Reported landings for PAU 3 are shown in Table 2 and Figure 2.

Since 2001, a redistribution of fishing effort within PAU 3 has been undertaken by the industry as a response to fears that the more accessible northern part of the fishery was being overfished. A voluntary subdivision was agreed by PauaMAC 3 which divided PAU 3 into four management zones (Table 3). A voluntary harvest cap is placed on each management zone and this cap is reviewed annually. Minimum harvest sizes (MHS) are also agreed for each zone in addition to the legislated Minimum Legal Size (MLS). These are also reviewed annually.

Figure 1: Map of fine scale statistical reporting areas for PAU 3.

Landings for PAU 3 are shown in Table 2.

Table 2: TACC and reported landings (t) of paua in PAU 3 from 1983–84 to present.

Table 3: Summary of the management zones within PAU3 as initiated by PauaMac3

Management zone (since 2001)	Area	Statistical area zone
3A	Clarence to Hapuku	P301–P304
3B	Hapuku to Conway	P305–P310
3D	Conway to Waipar	P311–P321
3E	Waipara to Witaki	P322–P329

Figure 2: Historical landings and TACC for PAU 3 from 1983–84 to present. QMS data from 1986–present.

1.2 Recreational fisheries

For further information on recreational fisheries refer to the introductory PAU Working Group Report. The New Zealand Recreational Marine Survey for 2011–12 estimated the recreational harvest for PAU 3 was 16.98 ton with a C.V. of 30%. For the purpose of the 2013 stock assessment, the Shellfish Working Group (SFWG) agreed to assume that the recreational catch rose linearly from 5t in 1974 to 17 t in 2013.

1.3 Customary fisheries

Estimates of customary catch for PAU 3 over the period where reliable estimates are available are shown in Table 4. Landings do not include the area between the Hurunui River and the South Shore (just north of Banks Peninsula), as Tangata Tiaki have not yet been appointed there. Many tangata whenua also harvest paua under their recreational allowance and these are not included in records of customary catch.

Table 4: Reported customary landings (t) of paua in PAU 3 from 2000–01 to 2008–09. Landings data exclude the area between the Hurunui and Pegasus Bay.

Year	Landings (t)
2000–01	1.64
2001–02	4.88
2002–03	3.84
2005–06	1.89
2006–07	4.56
2007–08	5.79
2008–09	8.23
2009–10	6.47
2010–11	7.45
2011–12	4.24
2012–13	12.74

1.4 Illegal catch

For further information on illegal catch refer to the introductory PAU Working Group Report. For the purpose of the 2013 stock assessment, the SFWG agreed to assume that illegal catches rose linearly from 5t in 1974 to 15 t in 2000, and remained at 15 t between 2001 and 2013.

1.5 Other sources of mortality

The Working Group agreed that handling mortality would not be included in the model. For further information on other sources of mortality refer to the introductory PAU Working Group Report.

2. BIOLOGY

For further information on paua biology refer to the introductory PAU Working Group Report. A summary of published estimates of biological parameters for PAU 3 is presented in Table 5.

Table 5: Estimates of biological parameters (*H. iris*) in PAU 3.

	Estimate	Source
<u>1. Natural mortality (M)</u>	0.135 (0.120-0.153)	Median (5-95% range) of posterior distribution for the base case model
<u>2. Weight = $a(\text{length})^b$ (Weight in g, length in mm shell length)</u>		
All	2.99×10^{-5} ^a ^b 3.303	Schiel & Breen (1991)
<u>3. Size at maturity (shell length)</u>		
	50% maturity at 82 mm (80-84)	Median (5-95% range) of posterior distribution for the base case model
	95% maturity at 102 mm (96-108)	Median (5-95% range) of posterior distribution for the base case model

3. STOCKS AND AREAS

For further information on stocks and areas refer to the introductory PAU Working Group Report.

4. STOCK ASSESSMENT

The stock assessment was implemented using a length-based Bayesian estimation model, with parameter point estimates based on the mode of the joint posterior distribution and uncertainty based on marginal posterior distributions generated from Markov chain-Monte Carlo (MCMC) simulations. The most recent stock assessment was conducted in 2014 for the fishing year ended 30 September 2013. The Shellfish WG determined a set of model runs where growth and natural mortality parameter values were fixed. The parameter values were thought to cover the plausible range of productivity assumptions for the stock. Markov chain-Monte Carlo (MCMC) simulations were conducted on a model agreed to by the SFWG. This particular model (6.1) estimated M within the model (with a lognormal prior with a mean of 0.1) but fixed the growth parameters at the medium value ($g_1=20$ mm, $g_2=6$ mm). On reviewing the results of the MCMC simulations the SFWG chose model 6.1 as the base case. The lack of comprehensive growth and length frequency data for PAU 3 and the lack of contrast in the CPUE series mean's uncertainty in the model outputs is higher than preferred.

4.1 Estimates of fishery parameters and abundance indices

Assumed prior distributions for model parameters are summarized in Table 6.

Table 6: A summary of estimated model parameters, lower bound, upper bound, type of prior, (U, uniform; N, normal; LN = lognormal), mean and C.V. of the prior.

Parameter	Prior	μ	C.V.	Bounds	
				Lower	Upper
$\ln(R0)$	U	–	–	5	50
M (Natural mortality)	LN	0.1	0.35	0.01	0.5
$\ln(q^i)$ (catchability coefficient of CPUE)	U	–	–	-30	0
$\ln(q^j)$ (catchability coefficient of PCPUE)	U	–	–	-30	0
L_{50} (Length at 50% maturity)	U	–	–	70	145
L_{95-50} (Length between 50% and 95% maturity)	U	–	–	1	50
D_{50} (Length at 50% selectivity for the commercial catch)	U	–	–	70	145
D_{95-50} (Length between 50% and 95% selectivity the commercial catch)	U	–	–	0.01	50
ϵ (Recruitment deviations)	N	0	0.4	-2.3	2.3

The observational data were:

1. A 1990-2001 standardised CPUE series based on CELR data.
2. A 2002-2012 standardised CPUE series based on PCELR data.
3. A commercial catch sampling length frequency series for 2000, 2002–2012.
4. Maturity at length data

4.1.1 Relative abundance estimates from standardised CPUE analyses

The 2013 stock assessment used two sets of standardised CPUE indices: one based on CELR data covering 1990–2001, and another based on PCELR data covering 2002–2013. For both series, standardised CPUE analyses were carried out using Generalised Linear Models (GLMs). A stepwise procedure was used to select predictor variables, with variables entering the model in the order that gave the maximum decrease in the residual deviance. Predictor variables were accepted into the model only if they explained at least 1% of the deviance.

For both the CELR and PCELR data, the Fisher Identification Number (FIN) was used in the standardisations instead of vessel, because the FIN is associated with a permit holder who may employ a suite of grouped vessels, which implies that there could be linkage in the catch rates among vessels operated under a single FIN.

For the CELR data there is ambiguity in what is recorded for estimated daily fishing duration, and therefore daily fishing duration has not been used in past standardisations as a measure of effort; instead the number of divers has been used. However, there is evidence that the fishing duration for a diver changes over time, and because of this a subset of the data was selected for which the recorded fishing duration was less ambiguous. The criteria used to subset the data were: (i) just one diver or, (ii) fishing duration ≥ 6 hours and number of divers ≥ 2 . This data subset was used for the CELR standardisation, using estimated daily catch and effort measured as either number of divers or fishing duration (both were offered to the standardisation model).

For the PCELR data the unit of catch was diver catch, with effort as diver duration. The diver duration measures the number of hours fished per diver day.

FIN codes were used to select a core group of fishers from the CELR data, with the requirement that there be a minimum of 6 records per year for a minimum of 2 years to qualify for the core fisher group. This retained 84% of the catch over 1990-2001. For the PCELR data the FIN was also used to select a core group of fishers, with the requirement that there be a minimum of 20 records per year for a minimum of 2 years. This retained 84% of the catch over 2002-2013.

For the CELR data, year was forced into the model and other predictor variables offered to the model were FIN, statistical area (018, 020, 022), month, fishing duration (as a cubic polynomial), number of divers, and a month:area interaction. Variables accepted into the model were fishing year, month, FIN, and fishing duration. Following previous standardisations, no interaction of fishing year with area was entered into the model as the stock assessment for PAU 3 is a single area model. However, a separate standardisation is also done where a year:area interaction is forced in. Forcing in a year:area interaction indicates that there are differences in standardised CPUE between the area 018 and the two areas 020 and 022. However, in the years where they differ there are very few records to estimate the year effects for areas 020 and 022.

For the PCELR data, fishing year was forced into the model and variables offered to the model were month, diver key, FIN statistical area, diver duration (third degree polynomial), and diving conditions. All the variables were accepted into the final model.

The standardised CPUE from the CELR data is flat from 1990 to 1994, shows a rise of 20% from 1995 to 1998, then declines for the next three years to 2001 (Figure 3–top). The standardised CPUE from the PCELR data shows a gradual decline of 10% from 2002 to 2013 (Figure 3–bottom).

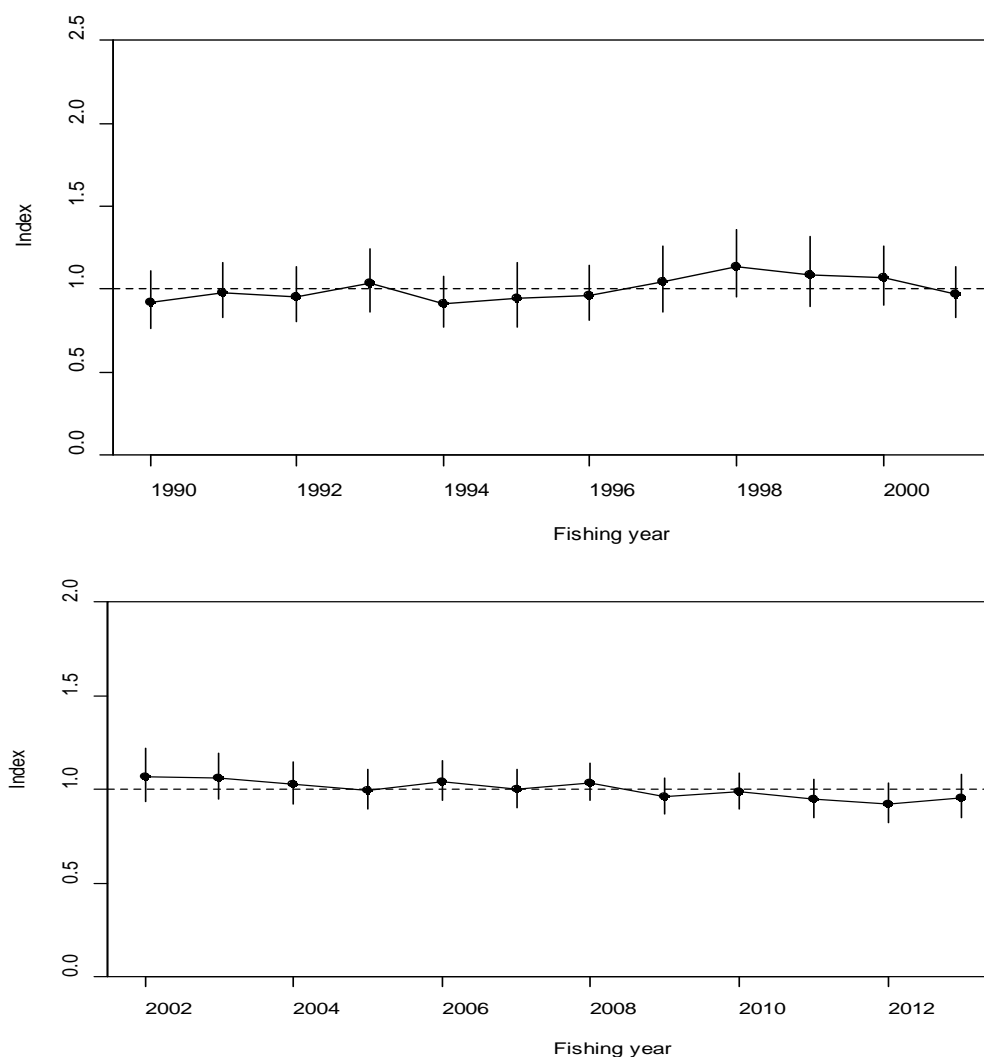

Figure 3: The standardised CPUE indices with 95% confidence intervals for the early CELR/FSU series (top panel) and the recent PCELR series (bottom panel).

4.2 Stock assessment methods

The 2013 PAU 3 stock assessment used the same length-based model as the 2012 PAU 5D assessment (Fu 2013). The model was described by Breen *et al.* (2003). This is the first assessment for PAU 3 using the length based Bayesian model (Fu 2013(in prep)).

The model structure assumed a single sex population residing in a single homogeneous area, with length classes from 70 mm to 170 mm, in 2 mm bins. Growth is length-based, without reference to age, mediated through a growth transition matrix that describes the probability of transition among length classes at each time step. Paua enter the model following recruitment and are removed by natural mortality and fishing mortality.

The models were run for the years 1965–2013. Catches were collated for 1974–2013, and were assumed to increase linearly between 1965 and 1973 from 0 to the 1974 catch level. Catches included commercial, recreational, customary, and illegal catch, and all catches occurred at the same time step.

Recruitment was assumed to take place at the beginning of the annual cycle, and length at recruitment was defined by a uniform distribution with a range between 70 and 80 mm. The stock-recruitment relationship is unknown for paua. A relationship may exist on small geographical scales, but not be apparent when large geographical scales are modelled (Breen *et al.* 2003). However, the Shellfish Working Group agreed to use a Beverton-Holt stock-recruitment relationship with steepness (h) of 0.75 for this assessment.

PAUA (PAU 3)

Maturity is not required in the population partition but is necessary for estimating spawning biomass. The model estimated proportions mature from length-at-maturity data. Growth and natural mortalities were also estimated within the model. The model estimated the commercial fishing selectivity, assumed to follow a logistic curve and asymptote at 1.

The growth data available to the PAU 3 assessment were collected from several sites in Banks Peninsula. Because most of the paua measured in this experiment were stunted, incorporating these data in the assessment would under-estimate the growth for the whole stock. There were also some growth measurements from an experiment conducted in Cape Campbell (within PAU 7) which is close to the northern boundary of PAU 3, but the sample size is too small to be useful. Therefore the growth parameters were fixed in this assessment.

The growth parameter were fixed at low ($g_1=15$ mm, $g_2=4.5$ mm), median ($g_1=20$ mm, $g_2=6$ mm), and high ($g_1=25$ mm, $g_2=7.5$ mm) values. The median values were based on the estimates of growth using the tag-recapture data from Cape Campbell (Fu 2014). The low and high values were loosely based on the range of growth estimates from assessments of other paua stocks. For each fixed value of the growth parameters, natural mortality was fixed at three levels, 0.1, 0.15, and 0.2. These values were considered to have covered the plausible range of natural mortality for paua. In total nine model runs were carried out. The growth and natural mortality parameter values aimed to evaluate the sensitivity of model results to key productivity assumptions and to estimate uncertainty in stock status. Each model run was considered an equally likely scenario. The models were fitted to the data with parameters estimated at the mode of their joint posterior distribution (MPD).

Markov chain-Monte Carlo (MCMC) simulations were conducted on a model agreed to by the SFWG in order to obtain a large set of samples from the joint posterior distribution. This particular model (6.1) estimated M within the model (with a lognormal prior with a mean of 0.1) but fixed the growth parameters at the medium value ($g_1=20$ mm, $g_2=6$ mm).

The assessment calculates the following quantities from the posterior distributions: the equilibrium spawning stock biomass with recruitment equal to the average recruitment over the period for which recruitment deviations were estimated (B_0); and the mid-season spawning and recruited biomass for 2013 (B_{2013} and B_{2013}^r) and for the projection period (B_{proj} and B_{proj}^r). This assessment also reports the following fishery indicators:

- $B\% B_0$ Current or projected spawning biomass as a percentage of B_0
- $B\% B_{msy}$ Current or projected spawning biomass as a percentage of B_{msy}
- $\Pr(B_{proj} > B_{msy})$ Probability that projected spawning biomass is greater than B_{msy}
- $\Pr(B_{proj} > B_{2013})$ Probability that projected spawning biomass is greater than $B_{current}$
- $B\% B_0^r$ Current or projected recruited biomass as a percentage of B_0^r
- $B\% B_{msy}^r$ Current or projected recruited biomass as a percentage of B_{msy}^r
- $\Pr(B_{proj} > B_{msy}^r)$ Probability that projected recruit-sized biomass is greater than B_{msy}^r
- $\Pr(B_{proj} > B_{2013}^r)$ Probability that projected recruit-sized biomass is greater than B_{2012}^r
- $\Pr(B_{proj} > 40\% B_0)$ Probability that projected spawning biomass is greater than 40% B_0
- $\Pr(B_{proj} < 20\% B_0)$ Probability that projected spawning biomass is less than 20% B_0
- $\Pr(B_{proj} < 10\% B_0)$ Probability that projected spawning biomass is less than 10% B_0
- $\Pr(U_{proj} > U_{40\% B_0})$ Probability that projected exploitation rate is greater than $U_{40\% B_0}$

4.3 Stock assessment results

For the nine model runs in which growth and natural mortality were fixed B_0 ranged from 1500 t to 2900 t, and $B_{current}$ ranged from 21% to 66% of B_0 (Table 7). All model runs showed an overall decreasing trend in spawning stock biomass but this trend has become slower in recent years (Figure 4). In general, models with higher values for M and growth had higher estimates of initial and current biomass, and models with lower M and growth had lower estimates of biomass.

When M was fixed at 0.1, the models fitted the CSLF and CPUE data poorly. Model fits improved markedly when M was increased to 0.15 or 0.20. The SFWG believed that 0.15 is probably more credible than 0.2 for the natural mortality of paua. Model fits and likelihood function values did not provide a clear distinction among low, median, or high growth values. Estimates of stock depletion levels were sensitive to the assumed value of the growth parameters.

For model (6.1), the posterior of M had a median of 0.14 with a 90% credible interval between 0.12 and 0.15. The posterior distributions of spawning stock biomass showed a gradual declining trend (Figure 5), estimated B_0 was about 2670 t (2470–2960t) and $B_{current}$ was about 52% (45–60%) of B_0 (Table 8). The SFWG agreed for this model to be adopted as the base case model, but noted that the model underestimates uncertainty in stock biomass and status because of uncertainty in growth.

The estimates of recruitment deviations showed a period of relatively low recruitment between 1980 the 1990 and recruitment in recent years (after 2002) has been above the long term average. Exploitation rates showed a gradual upward trend since the 2000s, and the estimated exploitation rate in 2013 was about 0.16 (0.09–0.14) (Table 8).

Model projections, assuming current catch levels and using recruitments re-sampled from the recent model estimates, suggested that the spawning stock abundance will slightly decrease to about 51% (41–63) of B_0 over the next three years (Table 9). The projections indicated that the probability of the spawning stock biomass being above the target (40% B_0) over the next three years is close to 100%.

Table 7: MPD estimates of B_0 , B_{2013} , and U_{2013} for models 3.1–3.3, 4.1–4.3, and 5.1–5.3.

Figure 4 [continued].

Figure 5: Posterior distributions of spawning stock biomass (top panel) and spawning stock biomass as a percentage of virgin level (bottom panel) from MCMC 6.1 (including projections). The box shows the median of the posterior distribution (horizontal bar), the 25th and 75th percentiles (box), with the whiskers representing the full range of the distribution.

4.4 Other factors

The assessment used CPUE as an index of abundance. The assumption that CPUE indexes abundance is questionable. The literature on abalone suggests that CPUE is difficult to use in abalone stock assessments because of serial depletion. This can happen when fishers deplete unfished or lightly fished beds and maintain their catch rates by moving to new areas. Thus CPUE stays high while the biomass is decreasing. In PAU 3, both the early and recent CPUE indices have shown a relatively flat trend (the recent CPUE decreased slightly). It is unknown to what extent the CPUE series tracks stock abundance in PAU 3. Information from commercial fishers indicates that the stock is in relatively good shape suggesting that the trend in CPUE series may be credible.

Even if the CPUE indices are credible, they are not very useful in informing estimates of B_0 in this case because they have shown a relatively flat trend. Therefore the catch sampling length frequencies are the most important observations that provide information on the initial size of the stock. The catch sampling coverage in PAU 3 is considered to be reasonably adequate and the CSLF data are likely to have been representative of the stock.

Another source of uncertainty is the catch data. The commercial catch is known with accuracy since 1985, but is probably not well estimated before that. In addition, non-commercial catch estimates are poorly determined. The estimate of illegal catch is uncertain. Anecdotal evidence suggested the recreational catch in PAU 3 is very likely to have increased substantially in recent years and could be much higher than what was assumed in the model. However, the increase in non-commercial catch (if it is true) has not been reflected in the recent CPUE indices, which showed an almost flat trend. One possible reason is that the commercial divers may have fished deeper than recreational fishers, and could be fishing on different sections of the population. If there is substantial bias in estimates of catches, the model could significantly under-estimate the stock depletion level. Therefore better information on the scale and trend in recreational catch needs to be collated for more accurate assessment of the stock status.

Another source of uncertainty is that fishing may cause spatial contraction of populations (Shepherd & Partington 1995), or that some populations become relatively unproductive after initial fishing (Gorfine & Dixon 2000). If this happens, the model will overestimate productivity in the population as a whole. Past recruitments estimated by the model might instead have been the result of serial depletion.

5. STATUS OF THE STOCK

Stock Structure Assumptions

PAU 3 is assumed to be a homogenous stock for purposes of the stock assessment however there is evidence to show this may not be correct (Naylor et al 2006).

- PAU 3 - *Haliotis iris*

Stock Status	
Year of Most Recent Assessment	2014
Assessment Runs Presented	MCMC 6.1 base case (M estimated, g_1 fixed at 20 mm and g_2 fixed at 6.0 mm)
Reference Points	Target: 40% B_0 (Default as per HSS) Soft Limit: 20% B_0 (Default as per HSS) Hard Limit: 10% B_0 (Default as per HSS) Overfishing threshold: $U_{40\%B_0}$
Status in relation to Target	B_{2013} estimated to be 52% B_0 : Very Likely (> 60%) to be at or above the target
Status in relation to Limits	Very Unlikely (< 10%) to be below the soft and hard limits
Status in relation to Overfishing	Overfishing is Very Unlikely (< 10%) to be occurring

Historical Stock Status Trajectory and Current Status

Posterior distributions of spawning stock biomass as a percentage of virgin level from MCMC 6.1 (including projections). The box shows the median of the posterior distribution (horizontal bar), the 25th and 75th percentiles (box), with the whiskers representing the full range of the distribution.

Trajectory of exploitation rate as a ratio $U/40B_0$ and spawning stock biomass as a ratio of B_0 from the start of assessment period 1965 to 2013 for MCMC 6.1 (base case). The vertical lines at 10%, 20%, 40% B_0 represent the hard limit, the soft limit, and the target respectively. $U/40B_0$ is the exploitation rate at which the spawning stock biomass would stabilise at 40% B_0 over the long term. Each point on trajectory represents the estimated annual stock status: the value on x axis is the mid-season spawning stock biomass (as a ratio of B_0) and the value on the y axis is the corresponding exploitation rate (as a ratio $U/40B_0$) for that year. The Estimates are based on MCMC median and the 2013 90% CI is shown by the cross line.

Fishery and Stock Trends

Recent Trend in Biomass or Proxy	Spawning stock biomass has shown an overall decreasing trend but this has become much slower in recent years.
Recent Trend in Fishing Mortality or Proxy	The exploitation rate has shown a gradual upward trend since the 2000s and was about 0.16 (0.09–0.14) in 2013.
Other Abundance Indices	Standardised CPUE remained relatively flat until the early 2000s, and has declined only slightly since then.
Trends in Other Relevant Indicators or Variables	Estimated recruitment was relatively low between 1980 and 1990 but since 2002 has been above the long term average.

Projections and Prognosis	
Stock Projections or Prognosis	The projected spawning stock abundance will slightly decrease over the next three years but will still be remaining above the target
Probability of Current Catch or TACC causing decline below Limits	Results from all model runs suggest it is very unlikely (< 10%) that current catch or TACC will cause a decline below the limits.

Assessment Methodology & Evaluation		
Assessment Type	Full quantitative stock assessment	
Assessment Method	Length based Bayesian model	
Assessment Dates	Latest: 2014	Next: 2017
Overall assessment quality (rank)	1 – High Quality	
Main data inputs (rank)	<ul style="list-style-type: none"> -Catch history -CPUE indices early series -CPUE indices later series -Commercial sampling length frequencies -Tag recapture data (to estimate growth) -Maturity at length data 	<ul style="list-style-type: none"> 1 – High Quality for commercial catch 2 – Medium or Mixed Quality for recreational catch, which is not believed to be fully representative over the history of the fishery 2 – Medium or Mixed Quality: not believed to be proportional to abundance 1 – High Quality 1 – High Quality 2 – Medium or Mixed Quality: not believed to be fully representative of the whole QMA 1 – High Quality
Data not used (rank)	N/A	
Changes to Model Structure and Assumptions	New model	
Major Sources of Uncertainty	<ul style="list-style-type: none"> - Very little growth data available and growth is not well known. - CPUE may not be a reliable index of abundance. - The model treats the whole of the assessed area of PAU 3 as if it were a single stock with homogeneous biology, habitat and fishing pressures. - Recreational catch in PAU 3 is very likely to have increased substantially in recent years and could be much higher than what was assumed in the model. 	

Qualifying Comments:

- The lack of comprehensive growth and length frequency data for PAU 3 and the lack of contrast in the CPUE series cause uncertainty in the model outputs.
- The SFWG agreed to adopt model 6.1 as the base case model, but noted that the model underestimates uncertainty in stock biomass and stock status because of uncertainty in growth.

PAUA (PAU 4) – Chatham Islands

(Haliotis iris)
Paua

1. FISHERY SUMMARY

PAU 4 was introduced into the Quota Management System in 1986–87 with a TACC of 261 t. As a result of appeals to the Quota Appeal Authority, the TACC was increased in 1995–96 to 326 t and has remained unchanged to the current fishing year (Table 1). There is no TAC for this QMA: before the Fisheries Act (1996) a TAC was not required. When changes have been made to a TACC after 1996, stocks have been assigned a TAC.

Table 1: Total allowable catches (TAC, t) allowances for customary fishing, recreational fishing, and other sources of mortality (t) and Total Allowable Commercial Catches (TACC, t) declared for PAU 4 since introduction into the QMS.

Year	TAC	Customary	Recreational	Other mortality	TACC
1986–1995	-	-	-	-	261
1995–present	-	-	-	-	326

1.1 Commercial fisheries

The fishing year runs from 1 October through to 30 September. On 1 October 2001 it became mandatory to report catch and effort on PCELRs using fine-scale reporting areas that had been developed by the New Zealand Paua Management Company for their voluntary logbook programme (see figure above).

At the beginning of the 2009–10 fishing year, reporting of catch in PAU 4 was changed from reporting in greenweight to reporting in meatweight. The TACC is still set in greenweight but fishers are now required to report greenweight catch that is estimated from the meatweight measured by the licensed fish receiver (LFR). The meatweight to greenweight conversion factor is 2.50 (equivalent to 40% meatweight recovery). The change was made to curb the practice of converting meatweight to landed greenweight after shucking to obtain artificially high recovery rates. It was also made to encourage catch spreading by making it commercially viable for fishers to harvest areas where shells are heavily fouled and meatweight recovery is low. Heavy fouling on shells is a problem that occurs in a number of areas around the Chatham Islands. Landings for PAU 4 are shown in Table 2 and Figure 1.

Table 2: TACC and reported landings (t) of puaa in PAU 4 from 1983–84 to the present.

Fishstock	Landings	TACC
1983–84*	409	-
1984–85*	278	-
1985–86*	221	-
1986–87*	267.37	261
1987–88*	279.57	269.08
1988–89*	284.73	270.69
1989–90	287.38	287.25
1990–91	253.61	287.25
1991–92	281.59	287.25
1992–93	266.38	287.25
1993–94	297.76	287.25

* FSU data.

Figure 1: Historical landings and TACC for PAU 4 from 1983–84 to the present. QMS data from 1986 to the present.

1.2 Recreational fisheries

There are no estimates of recreational catch for PAU 4. The 1996, 1999–2000 and 2000–01 national marine recreational fishing surveys did not include PAU 4.

1.3 Customary fisheries

There are no estimates of customary catch for PAU 4. For the 2004 stock assessment this catch was assumed to be zero. For further information on customary fisheries refer to the introductory PAU Working Group Report.

1.4 Illegal catch

There are no estimates of illegal catch for PAU 4. For the 2004 stock assessment this catch was assumed to be zero. For further information on illegal catch refer to the introductory PAU Working Group Report.

1.5 Other sources of mortality

For further information on other sources of mortality refer to the introductory PAU Working Group Report.

2. BIOLOGY

For further information on paua biology refer to the introductory PAU Working Group Report.

3. STOCKS AND AREAS

For further information on stocks and areas refer to the introductory PAU Working Group Report.

4. STOCK ASSESSMENT

4.1 Estimates of fishery parameters and abundance

A standardised CPUE analysis for PAU 4 (Fu 2010) from 1989–90 to 2007–08 was completed in February 2010.

The Shellfish Working Group (SFWG) agreed that, because of extensive misreporting of catch in PAU 4, catch and effort data from the Fisheries Statistical Unit and from the CELR and PCELR forms might be misleading in CPUE analyses and therefore, CPUE cannot be used as an index of abundance in this fishery.

4.2 Stock assessment 2004

The last stock assessment for PAU 4 was completed in 2004 (Breen & Kim 2004). A Bayesian length-based stock assessment model was applied to PAU 4 data to estimate stock status and yield. A reference period from 1991–93 was chosen: this was a period after which exploitation rates increased and then leveled off, and after which biomass declined somewhat and then stabilised. It was not intended as a target. Assessment results suggested that then-current recruited biomass was just above B_{AV} , but with high uncertainty (83% to 125%), and current spawning biomass appeared higher than S_{AV} , (130%), but with cautions related to maturity ogives. Projections suggested that 2007 recruited and spawning biomasses could be above B_{AV} , but this was uncertain.

The SFWG advised that major uncertainties in the assessment required the results to be treated with great caution. The major uncertainties included very sparse research diver survey data, misreported CELR and PCELR data, growth and length frequency data most likely not being representative of the whole population and the assumption that CPUE was an index of abundance.

In February 2010 the SFWG agreed that, because of the lack of adequate data as input into the Bayesian length-based model, a stock assessment for PAU 4 using this model was not appropriate.

4.3 Biomass estimates

There are no current biomass estimates for PAU 4.

4.4 Yield estimates and projections

There are no estimates of PAU 4

5. STATUS OF THE STOCKS

Stock Structure Assumptions

H. iris individuals collected from the Chatham Islands were found to be genetically distinct from those collected from coastal sites around the North and South Islands (Will & Gemmell 2008).

- PAU 4 - *Haliotis iris*

Stock Status	
Year of Most Recent Assessment	2004
Assessment Runs Presented	None
Reference Points	Target: 40% B_0 (Default as per HSS) Soft Limit: 20% B_0 (Default as per HSS) Hard Limit: 10% B_0 (Default as per HSS)
Status in relation to Target	Unknown
Status in relation to Limits	Soft Limit: Unknown Hard Limit: Unknown
Historical Stock Status Trajectory and Current Status	
In 2010 the SFWG rejected CPUE as an index of abundance, therefore the 2004 stock assessment (Breen & Kim 2004) is no longer considered reliable.	
Fishery and Stock Trends	
Recent Trend in Biomass or Proxy	-
Recent Trend in Fishing Mortality or Proxy	-
Other Abundance Indices	-
Trends in Other Relevant Indicators or Variables	-

Projections and Prognosis	
Stock Projections or Prognosis	The 2004 stock assessment is no longer considered reliable
Probability of Current Catch or TACC causing decline below Limits	Soft Limit: Unknown Hard Limit: Unknown
Assessment Methodology	
Assessment Type	Full Quantitative Stock Assessment, but subsequently rejected
Assessment Method	-
Main data inputs	-
Period of Assessment	Latest assessment: 2004 Next assessment: Unknown
Changes to Model Structure and Assumptions	-
Major Sources of Uncertainty	- Potential bias in RDSI - Assuming CPUE as a reliable index of abundance - Data are unreliable - Model is homogeneous - Model assumptions may be violated

Qualifying Comments
The 2004 full quantitative stock assessment is no longer considered reliable; i.e. the previous assessment has been rejected and there is currently no valid assessment for this stock.

PAUA (PAU 5A) – Fiordland

(*Haliotis iris*)
Paua

1. FISHERY SUMMARY

Prior to 1995, PAU 5A was part of the PAU 5 QMA, which was introduced into the QMS in 1986 with a TACC of 445 t. As a result of appeals to the Quota Appeal Authority, the TACC increased to 492 t in the 1991–92 fishing year; PAU 5 was then the largest QMA by number of quota holders and TACC. Concerns about the status of the PAU 5 stock led to a voluntary 10% reduction in the TACC in 1994–95. On 1 October 1995, PAU 5 was divided into three QMAs (PAU 5A, PAU 5B, and PAU 5D; see the figure above) and the TACC was divided equally among them; the PAU 5A quota was set at 148.98 t.

There is no TAC for PAU 5A (Table 1): before the Fisheries Act (1996) a TAC was not required. When changes have been made to a TACC after 1996, stocks have been assigned a TAC. No allowances have been made for customary, recreational or other mortality

Table 1: Total allowable catches (TAC, t) allowances for customary fishing, recreational fishing, and other sources of mortality (t) and Total Allowable Commercial Catches (TACC, t) declared for PAU 5 and PAU 5A since introduction to the QMS.

Year	TAC	Customary	Recreational	Other mortality	TACC
1986–1991*	-	-	-	-	445
1991–1994*	-	-	-	-	492
1994–1995*	-	-	-	-	442.8
1995–present	-	-	-	-	148.98

*PAU 5 TACC figures

1.1 Commercial fisheries

The fishing year runs from 1 October to 30 September.

On 1 October 2001 it became mandatory to report catch and effort on Paua Catch Effort Landing Returns (PCELRs) using fine-scale reporting areas that had been developed by the New Zealand Paua Management Company for their voluntary logbook programme (Figure 1).

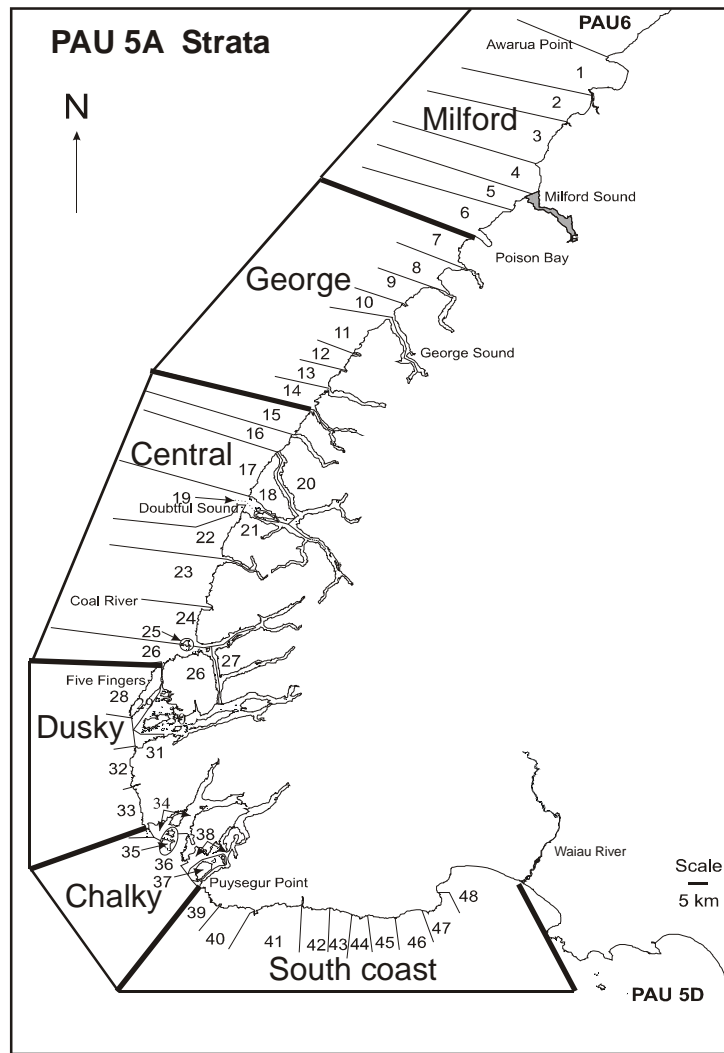

Figure 1: Map of puaa statistical areas, and voluntary management strata in PAU 5A.

Landings for PAU 5A are shown in Table 2 and Figure 2. Landings for PAU 5 are reported in the introductory PAU Working Group Report.

Table 2: TACC and reported landings (t) of puaa in PAU 5A from 1995–96 to the present from MHR returns.

Year	Landings	TACC
1995–96	139.53	148.98
1996–97	141.91	148.98
1997–98	145.22	148.98
1998–99	147.36	148.98
1999–00	143.91	148.98
2000–01	147.70	148.98
2001–02	148.53	148.98
2002–03	148.76	148.98
2003–04	148.98	148.98
2004–05	148.95	148.98
2005–06	148.92	148.98
2006–07	104.03	148.98
2007–08	105.13	148.98
2008–09	104.82	148.98
2009–10	105.74	148.98
2010–11	104.40	148.98
2011–12	106.23	148.98
2012–13	105.56	148.98

1.2 Recreational fisheries

For the purpose of the stock assessment model, the Shellfish Working Group (SFWG) agreed to assume that the 1974 recreational catch was 1 t, increasing linearly to 2 t in 2005. For further information on recreational fisheries refer to the introductory PAU Working Group Report.

Figure 2: Landings and TACC for PAU 5A from 1995–96 to the present. For historical landings in PAU 5 prior to 1995–96, refer to figure 1 and table 1 in the introductory PAU Working Group Report.

1.3 Customary fisheries

For the purpose of the stock assessment model, the SFWG agreed to assume that customary catch has been constant at 1 t. For further information on customary fisheries refer to the introductory PAU Working Group Report.

1.4 Illegal catch

There are no estimates of illegal catch for PAU 5A. For the purpose of the stock assessment model, the SFWG agreed to assume that illegal catches have been a constant 5 t. For further information on illegal catch refer to the introductory PAU Working Group Report.

1.5 Other sources of mortality

For further information on other sources of mortality refer to the introductory PAU Working Group Report.

2. BIOLOGY

For further information on paua biology refer to the introductory PAU Working Group Report. Biological parameters derived using data collected from PAU 5A are summarised in Table 3. Size-at-maturity, natural mortality and annual growth increment parameters were estimated within the assessment model.

Table 3: Estimates of biological parameters (*H. iris*). All estimates are external to the model.

Stock area	Estimate	Source
<u>1. Weight = a (length)^b (weight in kg, shell length in mm)</u>		
PAU 5A	a = 2.99E-08 b = 3.303	Schiel & Breen (1991)
<u>2. Size at maturity (shell length)</u>		
PAU 5A	50% mature: 93 mm 95% mature: 109 mm	Samples from Dusky, George, and Milford areas (Fu et al 2010)
<u>3. Estimated annual increments (both sexes combined)</u>		
PAU 5A	At 75 mm: 25.2 mm At 120 mm: 6.9 mm	Samples from Central, Dusky, George, Chalky and the South Coast (Fu et al 2010)

3. STOCKS AND AREAS

For further information on stocks and areas refer to the introductory PAU Working Group Report.

4. STOCK ASSESSMENT

The stock assessments for PAU 5A have previously been carried out at the QMA level. In 2010 the Shellfish Working Group decided to conduct the stock assessment for the two subareas of PAU 5A separately: a southern area including the Chalky and South Coast strata, and a northern area including the Milford, George, Central, and Dusky strata (Figure 1). The division was based on the availability of data, and differences in exploitation history and management initiatives.

4.1 Estimates of fishery parameters and abundance

Standardised CPUE data from CELR and PCELR records show a steady decline in CPUE in the Southern areas from 1990 to 2008, but an apparent increase since then (Figure 3, Upper graphs). CPUE shows a general increase in the northern areas from 1990 to 2003 but declined in 2004 and remained relatively stable since (Figure 3, Lower graphs). The stock assessment assumes that commercial CPUE is proportional to abundance; however, this may not be the case for paua stocks because serial depletion tends to maintain catch rates despite a declining biomass. Apparent stability in CPUE must therefore be interpreted with caution.

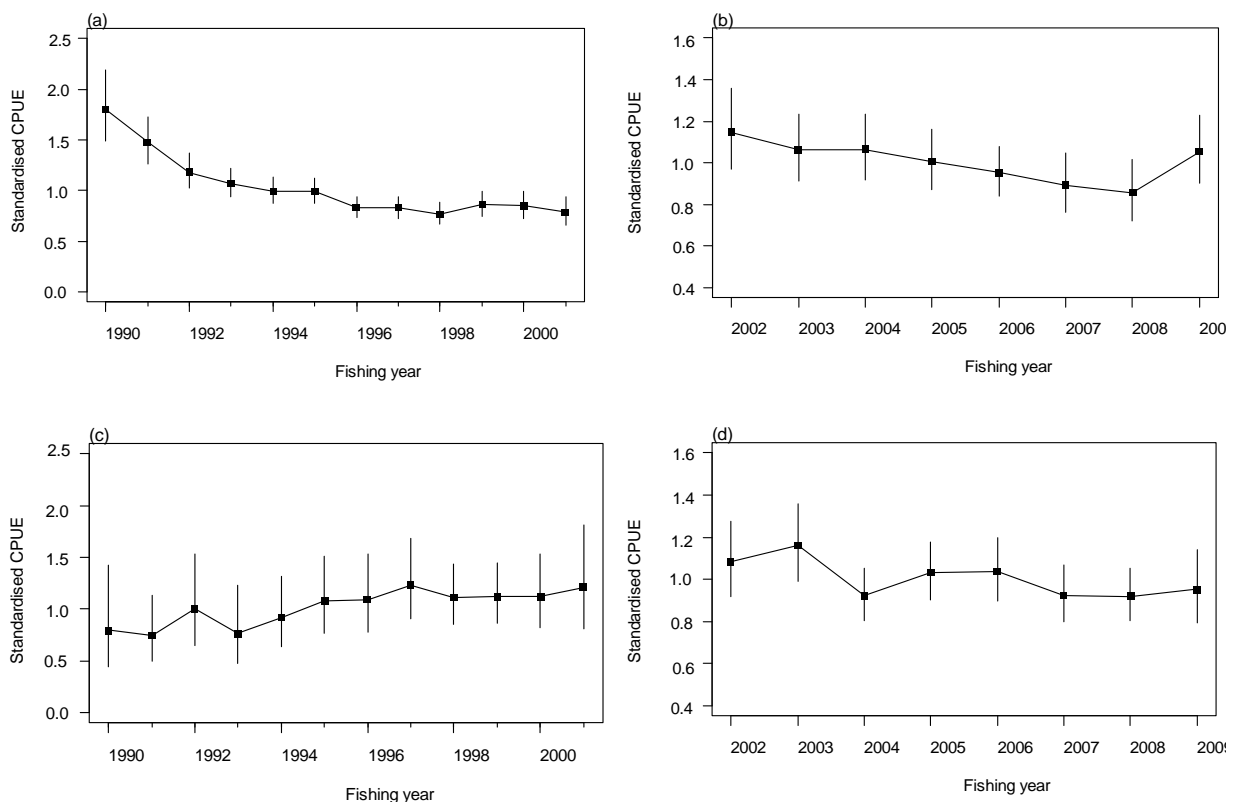

Figure 3: Standardised CPUE indices for the southern area of PAU 5A based on the CELR 1990–2001 (a) and PCELR 2002–2009 (b), and for the northern area based on CELR 1990–2001 (c) and PCELR 2002–2009 (d).

The abundance of paua in PAU 5A was also estimated from research diver surveys in 1996, 2002, 2003, 2006, and 2008–2010. Not every stratum was surveyed in each year, and before 2005–06 surveys were conducted only in the area from Dusky South. Concerns about the reliability of this data as an estimate of relative abundance instigated several reviews in 2009 (Cordue 2009) and 2010 (Haist 2010). The reviews assessed i) the reliability of the research diver survey index as a proxy for abundance and ii) whether the Research Diver Survey Index (RDSI), when used in the paua stock

assessment models, results in model outputs that do not adequately reflect the status of the stocks. Both reviews suggest that outputs from paua stock assessments using the RDSI should be treated with caution. For a summary of the conclusions from the reviews refer to the introductory PAU Working Group Report.

4.2 Biomass estimates

The 2010 assessment for the southern (Fu & McKenzie 2010a) and northern (Fu & McKenzie 2010b) areas of PAU 5A incorporated revision of the length-based model first used in 1999 for PAU 5B (Breen et al 2000a), and used in revised form for subsequent assessments in many paua stocks (Breen et al 2003, Breen & Kim 2005, McKenzie & Smith 2009). For more information on the model structure and the data used refer to Fu et al (2010) and Fu & McKenzie (2010ab).

The model partitioned the paua stock into a single sex population, with length classes from 70 mm to 170 mm, in groups of 2 mm. The stock was assumed to reside in a single, homogeneous area. The partition accounted for numbers of paua by length class within an annual cycle, where movement between length classes was determined by the growth parameters. Paua entered the partition following recruitment and were removed by natural mortality and fishing mortality.

The model simulates the population dynamics from 1965 to the current fishing year. Catches were available for 1974–2010 (commercial catch in 2010 was assumed to be the harvest cap), and were assumed to increase linearly between 1965 and 1973 from 0 to the 1974 catch level. Catches included commercial, recreational, customary, and illegal catch.

Recruitment was assumed to take place at the beginning of the annual cycle, and length at recruitment was defined by a uniform distribution with a range between 70 and 80 mm. Recruitment is modeled as an estimated baseline value with estimated annual deviations. No explicit stock-recruitment relationship was modelled in this assessment.

Maturity does not feature in the population partition. The model estimated proportions mature with the inclusion of length-at-maturity data. Growth and natural mortalities were also estimated within the model.

The models used two selectivities: the commercial fishing selectivity and research diver survey selectivity, both assumed to follow a logistic curve. From 2007 onward, following voluntary changes in the minimum harvest size, the commercial fishing selectivity was shifted by 5 mm for the southern area assessment, and 2 mm for the northern area assessment.

A point estimate of the mode of the joint posterior distribution (MPD) serves as the starting point for the Bayesian estimations and as the basis for some sensitivity tests. Markov Chain Monte Carlo (MCMC) simulations are used to estimate the marginal posterior distributions of model parameters, indicators and state of the stock. Indicators are based on current and projected states of the stock, and comparisons with a reference period, for both spawning and recruited biomass.

For both the Northern and Southern areas the data fitted in the assessment model were: (1) a standardised CPUE series based on the early CELR data, (2) a standardised CPUE series based on recent PCELR data, (3) a standardised research diver survey index (RDSI), (4) a research diver survey proportions-at-lengths series, (5) a commercial catch sampling length frequency series, (6) tag-recapture length increment data, and (7) maturity-at-length data. The catch history used as the model input included commercial, recreational, customary, and illegal catch. It was assumed that 80% of the non-commercial catch was taken from the southern area of PAU 5A, with the remainder being taken from the northern area.

For the Southern area the commercial catch history estimates were made under assumptions concerning the split of the catch between sub-stocks of PAU 5, and between subareas within PAU 5A. The base case model run has assumed 40% of the catch in Statistical Area 030 were taken from PAU 5A between 1985 and 1996. Estimates made under alternative assumptions (a lower bound of 18% and an upper bound of 61%) were used in sensitivity trials. The maturity and growth data included in the model were based on samples collected throughout PAU 5A, and the abundance and

PAUA (PAU 5A)

length frequency data were from Chalky and South Coast. The CPUE indices between 1990 and 2001 were based on catch effort data from Statistical Area 030. Only four years of catch sampling length frequencies (2002–2005) were included in the base case, as the sampling coverage is low since then and dubious before then. The additional catch sampling data were used in sensitivity trials.

For the Northern area the commercial catch history estimates between 1984 and 2010 were based on reported catch from Statistical Area 031 and 032, and estimates before 1984 were made using assumptions about the split of the catch between subareas within PAU 5A. The split proportions were inferred from the total estimated catch between 1984 and 1995 from Statistical Areas 030, 031, and 032, assuming that 18% (upper bound), 40% (base case), or 61% (lower bound) of the annual catch in 030 was taken from PAU 5A. The maturity and growth data included in the model were based on samples collected throughout PAU 5A, and the abundance and length frequency data were from Milford, George, Central, and Dusky. As for the southern area assessment only four years of catch sampling length frequencies (2002–2005) were included, as the sampling coverage has been low since then and is unreliable before 2002. The decision was made following the southern area assessment.

A base case model was chosen by the SFWG for each of the assessments. For the southern area, the base case used the catch vector estimated under the base case assumption (the lower bound and upper bound estimates were investigated in sensitivities), and included CSLF data for 2002–2005 (the full CSLF series were used in the sensitivity). Recruitment deviations were estimated for 1986–2006. The commercial fishing selectivity was shifted by 5 mm after 2007 in line with the increase of the minimum harvest size (MHS). Each dataset was weighted so that the standard deviations of the normalised residuals were close to 1.0 for each dataset.

For the northern area, the base case used the catch vector estimated under the base case assumption and included CSLF data for 2002–2005. Recruitment deviations were estimated for 1982–2006. The initial run suggested that the model fitted poorly to the recent CPUE indices. Therefore two alternative runs were proposed: a base case model which up-weighted the recent CPUE series, and a hyperstability model which assumed a non-linear relationship between CPUE and vulnerable biomass. Another source of uncertainty relates to changes in fishing selectivity due to an increase in Minimum Harvest Size in 2007, which varied by region. The base case and hyperstability model assumed a shift of fishing selectivity by 2 mm since 2007, with alternatives of 3 (model 6.1) and 4 mm (model 6.2) investigated in sensitivity trials.

The assessment reported B_{init} , the spawning stock biomass at the end of initialisation phase, and B_0 the equilibrium spawning stock biomass assuming that recruitment is equal to the average recruitment from the period for which recruitment deviation were estimated. B_0 will differ from B_{init} if estimated average recruitment deviates from base recruitment. The assessment used the ratio of current and projected spawning stock biomass ($B_{current}$ and B_{2012}) to B_0 as preferred indicators of stock status (B_{init} was considered to have little biological meaning). The assessment also reported $B_{current}^r$, B_{init}^r , and B_0^r being the current, initial, and virgin recruit-sized biomass respectively.

Recent practice has been to define a reference period in which biomass was stable, catches were good and the exploitation rate was sustainable. However, different biomass trajectories in sensitivity runs suggested that this approach was inappropriate for this assessment. Therefore S_{AV} and B_{AV} were not used as indicators in this assessment.

Projections were made up to 2012 (a three- and two-year projection for the southern and northern area assessment respectively). Recruitments for projections were obtained by randomly re-sampling model estimates from 1996 to 2006. Catch assumed in the projection included the 2009–10 harvest cap and the estimates for recreational, customary and illegal harvest. Catches were not fully taken if the corresponding exploitation rate exceeded the upper bound of 0.65. For the northern area assessment, projections made under current catch levels suggested that biomass is likely to decrease over the next two years, therefore additional projections were made assuming reduced catch levels, and the model output $Pr(B_{2012} > B_{2010})$, the probability that projected spawning biomass in 2012 would be higher than in 2010.

4.2.1 Stock assessment results

Southern Area

For the southern area, the base case fitted most data credibly. However, it was unable to fit the steep decline in the CPUE between 1990 and 1994, and was also unable to explain the inter-annual changes in the observed RDSI. The estimates of recruitment were lower than average in the late 1980s and about average through the 1990s. Exploitation rate was generally below 0.4 but was variable. The exploitation rate has been high since the late 1990s, but showed decreases over the last few years, in line with the reduction of catch levels.

The summaries of indicators from the base case for the southern area assessment are shown in Table 4. The median of the posterior of B_0 was estimated to be 1155 t. The posterior trajectory of spawning stock biomass is shown in Figure 4. Current estimates from the base case suggest that the spawning stock population in 2009 ($B_{current}$) was about 35% (28–42%) B_0 , and recruit-sized stock abundance ($B_{current}^r$) was about 24% (19–29%) of the initial state (B_0^r).

The projection suggested that the stock abundance would continue to increase over the next three years and the spawning stock biomass in 2012 was projected to be about 39% (31–50%) of B_0 , or 14% (2–26%) more than current (2009) levels (Table 5). Based on the 1000 posterior samples, the probability that the spawning stock biomass would decrease in three year's time is less than 7%.

The effects of using alternative catch history estimates (upper and lower-bound) were also investigated. The MPD estimates of $B_{current}$ ranged from 30% to 52% of B_0 for those estimates.

Table 4: Summaries of the marginal posterior distributions of indicators for the base case of the southern area assessment. Columns show the 5th and 95th quantiles, median, minimum and maximum of each distribution. Biomass is in tonnes.

	Min	5%	Median	95%	Max
B_0	996	1066	1155	1252	1345

$U_{current}$	0.15	0.18	0.22	0.25	0.29

Table 5: Summary of key indicators from the projection for the base case of the southern area assessment: projected biomass as a percentage of the virgin and current stock status, for spawning stock and recruit-sized biomass, respectively.

Projection	2009	2010	2011	2012
% B_0	34.6 (27.3–43.9)	35.6 (27.8–45.2)	37.5 (29.3–47.7)	39.4 (30.9–50)
% B_0^r	20.7 (16.3–25.8)	21.5 (16.7–27.1)	22.2 (17.1–28.4)	23.2 (17.9–30)
% $B_{current}$	100 (100–100)	103 (99–107)	108 (100–117)	114 (102–126)
% $B_{current}^r$	100 (100–100)	104 (99–110)	108 (100–117)	112 (103–123)

Figure 4: Posterior distributions of spawning stock biomass (including projection) as a percentage of B_0 for the southern area assessment. The box shows the median of the posterior distribution (horizontal bar), the 25th and 75th percentiles (box), with the whiskers representing the full range of the distribution. The boxes to the right of the dashed line indicate the projected spawning biomass to 2012 for each model assuming current catch level.

Northern area

The base case model suggested that recruitment was lower than average in the early 1980s and above average through the 1990s, and that the exploitation rate has increased since the mid 1990s, and remained at relatively high levels over the last few years. The initial run of the base case model suggested that the model fitted poorly to the recent CPUE indices. Therefore two alternative runs were proposed by the SFWG: a base case model which up-weighted the recent CPUE series, and a hyperstability model which assumed a non-linear relationship between CPUE and vulnerable biomass.

The summaries of indicators from the base case are shown in Table 6. The estimated spawning stock population in 2010 ($B_{current}$) is 41% (34–50%) B_0 , and the recruit-sized stock abundance ($B^r_{current}$) is 26% (21–33%) of initial state (B^r_0). Estimates from the hyperstability model suggest that $B_{current}$ is 26% (21–35%) B_0 , and $B^r_{current}$ is 16% (12–22%) of B^r_0 (Table 7).

Table 6: Summaries of the marginal posterior distributions of indicators for the base case of the northern area assessment. Columns show the 5th and 95th quantiles, median, minimum and maximum of each distribution. Biomass is in tonnes.

	Min	5%	Median	95%	Max
B_0	913	960	1012	1065	1123
B_{init}	727	782	858	961	1065
$B_{current}$	300	351	417	498	580
$B_{current} / B_0$	0.29	0.35	0.41	0.49	0.54
B^r_0	694	737	787	843	926
B^r_{init}	545	613	670	734	809
$B^r_{current}$	150	175	207	250	305
$B^r_{current} / B^r_0$	0.18	0.22	0.26	0.31	0.38
$U_{current}$	0.22	0.27	0.31	0.36	0.41

Table7: Bayesian median and 95% credible intervals of key indicators for the hyperstability model for the northern area assessment. Biomass is in tonnes.

Model	B_0 (t)	B^r (t)	B_{2010} (% B_0)	B^r_{2010} (% B^r_0)
Hyperstability	989 (923–1065)	805 (727–887)	26.4 (20.5–34.7)	16.1 (11.8–22.3)

Assuming greater selectivity shifts of 2 to 4 mm since 2007 led to more optimistic estimates of stock status; the median of $B_{current}$ (% B_0) ranged from 41% to 50% for the base case, and from 26% to 30% for the hyperstability model. The posterior trajectories of spawning stock biomass for the base case and hyperstability models are shown in Figures 5 and 6.

Figure 5 Posterior distributions of spawning stock biomass trajectory for base case (black), 6.1 (grey) Base case, selectivity shifted by 3mm from 2007), and 6.2 (orange), Base case, selectivity shifted by 4mm from 2007) for the northern area assessment. The box shows the median of the posterior distribution (horizontal bar), the 25th and 75th percentiles (box), with the whiskers representing the full range of the distribution. The boxes to the right of the dashed line indicate the projected spawning biomass to 2012 for each model assuming current catch level. Model 6.1 and 6.2, base case but commercial selectivity shifted by 3 and 4 mm respectively from 2007.

The projection made for the base case suggested that the stock abundance would decrease slightly over the next two years. The projected spawning stock biomass in 2012 has a median of 40% of B_0 , about 3% less than the current (2009) level (Table 8). The probability that the spawning stock biomass will increase in two year's time ($\Pr\{B_{2012} > B_{current}\}$) is about 22%. The hyperstability model predicted a larger decline in abundance, with B_{2012} predicted to be 6% less than current state (Table 8). Projections made with alternative future catches suggested that $\Pr\{B_{2012} > B_{current}\}$ would increase with reduced catch levels. For the base case, $\Pr\{B_{2012} > B_{current}\}$ would be greater than 50% if the catch is reduced by 10 t each year for the next two years; for the hyperstability model, catch shelving of up to 20 t each year is required. Projections made with larger selectivity shifts have all predicted declines in future stock abundance, but generally with smaller risks.

Figure 6: Posterior distributions of spawning stock biomass trajectory for hyperstability model (black), 8.1 (gray), and 8.2 (orange). The box shows the median of the posterior distribution (horizontal bar), the 25th and 75th percentiles (box), with the whiskers representing the full range of the distribution. The boxes to the right of the dashed line indicate the projected spawning biomass to 2012 for each model assuming current catch level. Model 8.0 and 8.2, hyperstability model but commercial selectivity shifted by 3 and 4 mm respectively from 2007.

Table 8: Bayesian median and 95% credible intervals of key indicators of projection assuming various future catch levels, the base case and hyperstability models for the northern area assessment.

Model	Catch	$B_{2012} (\% B_0)$	$B_{2012} (\% B_{2010})$	$Pr(B_{2012} > B_{2010})$
Base case	74 330	40.0 (31.8–49.5)	0.97 (0.89–1.05)	0.218
	69 330	40.7 (32.5–50.2)	0.99 (0.91–1.06)	0.364
	64 330	41.4 (33.2–50.8)	1.00 (0.93–1.08)	0.520
Hyperstability	74 330	24.7 (19.1–33.3)	0.94 (0.82–1.06)	0.140
	64 330	25.4 (19.1–34.7)	0.97 (0.85–1.07)	0.278
	54 330	26.8 (19.7–36.1)	1.01 (0.89–1.12)	0.598

The Shellfish Working Group was satisfied that the stock assessment for both the Southern and Northern areas of PAU 5A was reliable based on the available data. It was agreed by the SFWG that the range of estimated indicators for both the base case and hyperstability models used in the Northern area assessment were acceptable, but where within the range of estimates the actual status of the fishery is located is not clear.

4.3 Yield estimates and projections

No estimate of *MCY* has been made for PAU 5A.

No estimate of *CAY* has been made for PAU 5A.

4.5 Other factors

A number of factors affected the overall validity of the assessment.

There were uncertainties in the estimated catch history for PAU 5A and its subareas before 1995. The results from the southern area assessment suggested that estimates of stock status are sensitive to the

range of assumptions made for the estimated catch history. For the northern area of PAU 5A, the commercial catch history is well determined back to 1984, although uncertainty exists for the pre-1984 catch, which is expected to have minor effects on the overall assessment. There is little information on the historical catches in Fiordland, but anecdotal evidence suggested that the catch between 1981 and 1984 was about 60–70 t annually (Storm Stanley pers. comm.). The lower and upper-bound catch estimates used in the assessment may have encompassed many of the uncertainties in the historical catches. In addition, non-commercial catch estimates are also very uncertain, and large differences may exist between the catches assumed and the catch actually taken. In both assessments, the modelled area is treated as if it were a single stock with homogeneous biology, habitat and fishing pressure. It is assumed that:

- recruitment affects the modelled area in the same way;
- natural mortality does not vary by length or year in the modelled area;
- growth has the same mean and variance in the modelled area, although in reality growth may be stunted in some areas and fast in others.

Variation in growth is addressed to some extent by having a stochastic growth transition matrix based on increments observed in several different sites. Similarly, the length frequency data are integrated across samples from many places. An open question is whether a model fitted to data aggregated from a large area, within which smaller populations respond differently to fishing, results in credible estimates of the response of the aggregated sub-populations.

This effect is likely to make model results optimistic. For instance, if some local stocks are fished very hard and others are not fished, recruitment failure can result due to the depletion of spawners, because spawners must breed close to each other, and because the dispersal of larvae may be limited. Recruitment failure is a common observation in abalone fisheries internationally. Local processes may decrease recruitment, an effect that cannot be accounted for in the current model.

A significant source of uncertainty is that fishing may cause spatial contraction of populations or that some populations become relatively unproductive after initial fishing due, for example, to reductions in density that may impede successful spawning. If this happens, the model will overestimate productivity in the population as a whole. Historical catches may have been interpreted in the model as good recruitments, whereas they may actually have been the result of serial depletion.

5. STATUS OF THE STOCKS

Stock Structure Assumptions

A genetic discontinuity between North Island and South Island paua populations was found approximately around the area of Cook Strait (Will & Gemmell 2008).

- **PAU 5A - *Haliotis iris***

Stock Status	
Year of Most Recent Assessment	2010
Assessment Runs Presented	Southern Area: base case model Northern Area: base case and hyperstability models
Reference Points	Target: 40% B_0 (Default as per HSS) Soft Limit: 20% B_0 (Default as per HSS) Hard Limit: 10% B_0 (Default as per HSS)
Status in relation to Target	Southern Area: Spawning stock biomass was estimated at 35% B_0 . Northern Area: Spawning stock biomass was estimated at 41% B_0 by the base case model but only at 26% B_0 by the hyperstability model. It was agreed by the SFWG that the range of estimated indicators for both the base case and hyperstability models used in the Northern area assessment were acceptable, but where within the range

	of estimates the actual status of the fishery is located is not clear. The status in reflection to the target is therefore unknown.
Status in relation to Limits	<p>Southern Area: Very Unlikely (< 10%) to be below the soft and hard limits. Spawning stock biomass was estimated at 35% B_0.</p> <p>Northern Area: Unlikely (< 40%) to be below the soft limit. Very Unlikely (< 10%) to be below the hard limit.</p>

Historical Stock Status Trajectory and Current Status

Posterior distributions of spawning stock biomass (including projection) as a percentage of B_0 for the southern area assessment. The box shows the median of the posterior distribution (horizontal bar), the 25th and 75th percentiles (box), with the whiskers representing the full range of the distribution. The boxes to the right of the dashed line indicate the projected spawning biomass to 2012 for each model assuming current catch level.

Posterior distributions of spawning stock biomass trajectory for base case (black), 6.1 (gray), and 6.2 (orange) for the northern area assessment. The box shows the median of the posterior distribution (horizontal bar), the 25th and 75th percentiles (box), with the whiskers representing the full range of the distribution. The boxes to the right of the dashed line indicate the projected spawning biomass to 2012 for each model assuming current catch level. Model 6.1 and 6.2, base case but commercial selectivity shifted by 3 and 4 mm respectively from 2007.

Posterior distributions of spawning stock biomass trajectory for hyperstability model (black), 8.1 (gray), and 8.2 (orange) for the northern area assessment. The box shows the median of the posterior distribution (horizontal bar), the 25th and 75th percentiles (box), with the whiskers representing the full range of the distribution. The boxes to the right of the dashed line indicate the projected spawning biomass to 2012 for each model assuming current catch level. Model 8.0 and 8.2, hyperstability model but commercial selectivity shifted by 3 and 4 mm respectively from 2007.

Fishery and Stock Trends	
Recent Trend in Biomass or Proxy	Southern: Spawning stock biomass generally declined from 2002 to 2007 but has been increasing up to 2009. Northern: Spawning stock biomass declined from 1997 until 2010
Recent Trend in Fishing Mortality or Proxy	-
Other Abundance Indices	-
Trends in Other Relevant Indicators or Variables	-

Projections and Prognosis	
Stock Projections or Prognosis	Southern: Spawning stock biomass in 2012 is projected to be about 39% (31–50%) of B_0 , or 14% (2–26%) more than the 2009 levels. The probability that the spawning stock biomass will decrease in three year’s time is less than 7%. Northern: The base case model projected spawning stock biomass in 2012 to be 40% of B_0 , about 3% less than current level. The probability that the spawning stock biomass would increase by 2012 is about 22%. The hyperstability model predicted a larger decline in abundance, with B_{2012} predicted to be 6% less than current state. Projections made with alternative future catches suggested that $\Pr\{ B_{2012} > B_{current} \}$ will increase with reduced catch levels. For the base case, $\Pr\{ B_{2012} > B_{current} \}$ will be greater than 50% if the catch is reduced by 10 t each year for the next two years; for the hyperstability model, catch shelving of up to 20 t each year is required.
Probability of Current Catch or TACC causing decline below Limits	Soft Limit: Southern - Very Unlikely (< 10%) Northern - Unlikely (< 40%) Hard Limit: Southern - Very Unlikely (< 10%) Northern - Very Unlikely (< 10%)

Assessment Methodology	
Assessment Type	Full quantitative stock assessment
Assessment Method	Length-based Bayesian model
Main data inputs	CPUE, RDSI, CSLF, RDLF, catch history
Period of Assessment	Latest assessment: 2010 Next assessment: Unknown
Changes to Model Structure and Assumptions	- Previous assessment in 2005 was for a single QMA. The QMA was assessed as two separate areas for the 2010 assessment
Major Sources of Uncertainty	- Potential bias in RDSI - CPUE as a reliable index of abundance - Data are not reliable - Model is homogeneous - Model assumptions may be violated

PAUA (PAU 5B) - Stewart Island

(*Haliotis iris*)

Paua

1. FISHERY SUMMARY

Before 1995, PAU 5B was part of the PAU 5 QMA, which was introduced into the QMS in 1986 with a TACC of 445 t. As a result of appeals to the Quota Appeal Authority, the TACC increased to 492 t in the 1991–92 fishing year; PAU 5 was then the largest QMA by number of quota holders and TACC. Concerns about the status of the PAU 5 stock led to a voluntary 10% reduction in the TACC in 1994–95. On 1 October 1995, PAU 5 was divided into three QMAs (PAU 5A, PAU 5B, and PAU 5D; see the figure above) and the TACC was divided equally among them; the PAU 5B TACC was set at 148.98 t.

On 1 October 1999 a TAC of 155.98 t was set for PAU 5B, comprising a TACC of 143.98 t (a 5 t reduction) and customary and recreational allowances of 6 t each. The TAC and TACC have been reduced twice since then and the current TAC is 105 t with a TACC of 90 t, customary and recreational allowances at 6 t each and an allowance of 3 t for other mortality (Table 1.)

Table 1: Total allowable catches (TAC, t) allowances for customary fishing, recreational fishing, and other sources of mortality (t) and Total Allowable Commercial Catches (TACC, t) declared for PAU 5 and PAU 5B since introduction into the QMS.

Year	TAC	Customary	Recreational	Other mortality	TACC
1986–1991*	-	-	-	-	445
1991–1994*	-	-	-	-	492
1994–1995*	-	-	-	-	442.8
1995–1999	-	-	-	-	148.98
1999–2000	155.9	6	6	-	143.98
2000–2002	124.87	6	6	-	112.187
2002–present	105	6	6	3	90

*PAU 5 TACC figures

1.1 Commercial fishery

The fishing year runs from 1 October to 30 September.

Concerns about the status of the stock led to the commercial fishers agreeing to voluntarily reduce their Annual Catch Entitlement (ACE) by 25t for the 1999/00 fishing year. This shelving continued for the 2000/01 and 2001/02 fishing years at a level of 22 t but was discontinued at the beginning of the 2002/03 fishing year (Table 2).

PAU (PAU 5B)

On 1 October 2001 it became mandatory to report catch and effort on Paua Catch Effort Landing Returns (PCELRs) using fine-scale reporting areas that had been developed by the New Zealand Paua Management Company for their voluntary logbook programme (Figure 1).

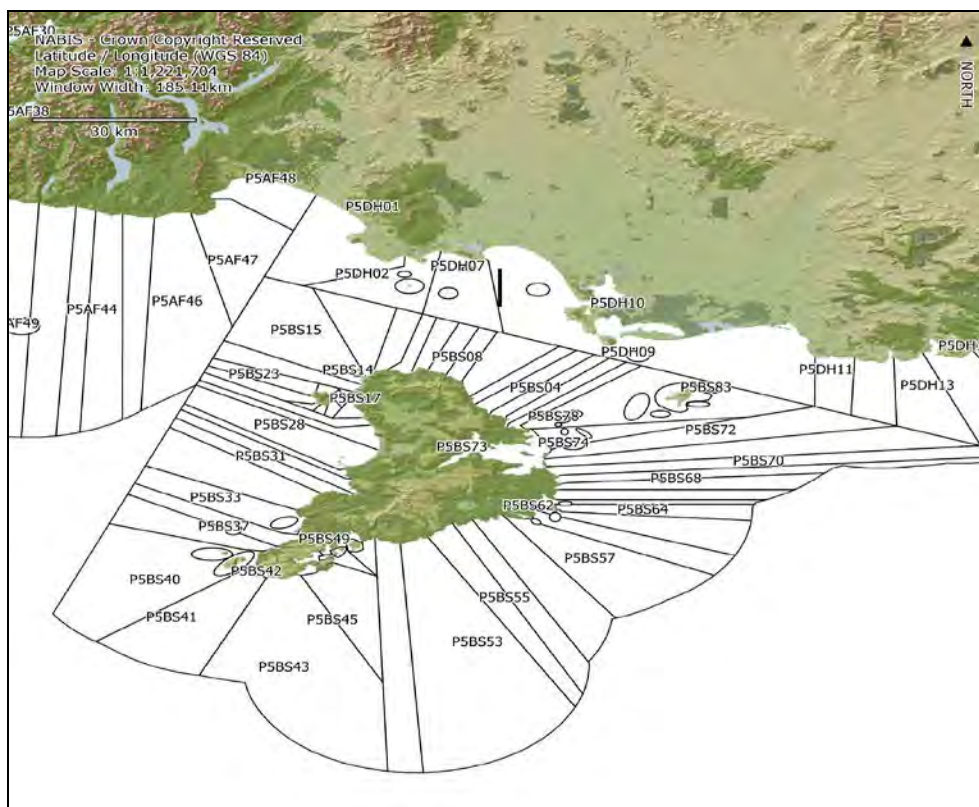

Figure 1: Map of fine scale statistical reporting areas for PAU 5B.

Landings for PAU 5B are shown in Table 2 and Figure 2. Landings for PAU 5 are reported in the introductory PAU Working Group Report.

Table 2: TACC and reported commercial landings (t) of paua in PAU 5B, 1995–96 to present, from QMR and MHR returns.

Year	Landings	TACC
1995–96	144.66	148.98
1996–97	142.36	148.98
1997–98	145.34	148.98
1998–99	148.55	148.98
1999–00	118.07	143.98
2000–01	89.92	112.19
2001–02	89.96	112.19
2002–03	89.86	90.00
2003–04	90.00	90.00
2004–05	89.97	90.00
2005–06	90.47	90.00
2006–07	89.16	90.00
2007–08	90.21	90.00
2008–09	90.00	90.00
2009–10	90.23	90.00
2010–11	89.67	90.00
2011–12	89.59	90.00
2012–13	90.58	90.00

Figure 2: Historical landings and TACC for PAU 5B from 1995–96 to present. For historical landing in PAU 5 before 1995–96 refer to figure 1 and table 1 in the introductory PAU Working Group Report.

1.2 Recreational fisheries

The New Zealand Recreational Marine Survey for 2011–12 estimated that the recreational harvest for PAU 5B was 0.82 t with a CV of 50%. For the 2013 assessment, the SFWG agreed to assume that the recreational catch rose linearly from 1 t in 1974 to 5 t in 2006, and remained at 5 t between 2007 and 2013. For further information on recreational fisheries refer to the introductory PAU Working Group Report.

1.3 Customary fisheries

The SFWG agreed to assume for the 2013 assessment that customary catch has been 1 t for the whole period modelled. For further information on customary fisheries refer to the introductory PAU Working Group Report.

1.4 Illegal catch

Illegal catch was estimated by the Ministry of Fisheries to be 15 t, but “Compliance express extreme reservations about the accuracy of this figure.” The SFWG agreed to assume for the 2013 assessment that illegal catch was zero before 1986, then rose linearly from 1 t in 1986 to 5 t in 2006, and remained constant at 5 t between 2007 and 2013. For further information on illegal catch refer to the introductory PAU Working Group Report.

1.5 Other sources of mortality

For further information on other sources of mortality refer to the introductory PAU Working Group Report.

2. BIOLOGY

For further information on paua biology refer to the introductory PAU Working Group Report. A summary of biological parameters used in the PAU 5B assessment is presented in Table 3.

3. STOCKS AND AREAS

For further information on stocks and areas refer to the introductory PAU Working Group Report.

Table 3: Estimates of biological parameters (*H. iris*).

	Estimate	Source
<u>1. Natural mortality (M)</u>	0.10 (CV 0.10)	Assumed prior probability distribution
<u>2. Weight = $a(\text{length})^b$ (Weight in g, length in mm shell length).</u>		
	All	
	a b	
	2.99×10^{-5} 3.303	Schiel & Breen (1991)
<u>3. Size at maturity (shell length)</u>		
	50% maturity at 91 mm	Naylor (NIWA unpub. data)
	95% maturity at 133mm	Naylor (NIWA unpub. data)
<u>4. Growth parameters (both sexes combined)</u>		
	Growth at 75 mm	Growth at 120 mm
	26.1 mm (24.8 to 27.2)	6.9 mm (6.5–7.3)
		Median (5–95% range) of posterior distributions estimated by the assessment model

4. STOCK ASSESSMENT

The stock assessment was done with a length-based Bayesian estimation model, with parameter point estimates based on the mode of the joint posterior distribution and uncertainty estimated from marginal posterior distributions generated from Markov chain-Monte Carlo simulations. The most recent stock assessment was conducted in 2014 for the fishing year ended 30 September 2013. A base case model (0.1) was chosen from the assessment. The SFWG also suggested a sensitivity run (model 0.4) which assumed a uniform prior on M to explore the influence of this prior on the estimates of stock status.

4.1 Estimates of fishery parameters and abundance

Parameters estimated in the assessment model and their Bayesian prior distributions are summarized in Table 4.

Table 4: A summary of estimated model parameters, lower bound, upper bound, type of prior, (U, uniform; N, normal; LN = lognormal), mean and c.v. of the prior.

Parameter	Prior	μ	c.v.	Bounds	
				Lower	Upper
$\ln(R0)$	U	–	–	5	50
M (natural mortality)	LN	0.1	0.35	0.01	0.5
g_1 (Mean growth at 75 mm)	U	–	–	1	50
g_2 (Mean growth at 120 mm)	U	–	–	0.01	50
ϕ (CV of mean growth)	U	–	–	0.001	1
$\ln(q^I)$ (catchability coefficient of CPUE)	U	–	–	-30	0
$\ln(q^J)$ (catchability coefficient of PCPUE)	U	–	–	-30	0
L_{50} (Length at 50% maturity)	U	–	–	70	145
L_{95-50} (Length between 50% and 95% maturity)	U	–	–	1	50
D_{50} (Length at 50% selectivity for the commercial catch)	U	–	–	70	145
D_{95-50} (Length between 50% and 95% selectivity for the commercial catch)	U	–	–	0.01	50
ϵ (Recruitment deviations)	N	0	0.4	-2.3	2.3

The observational data were:

1. A 1990–2001 standardised CPUE series based on CELR data.
2. A 2002–2012 standardised CPUE series based on PCELR data.
3. A commercial catch sampling length frequency series for 1998, 2002–04, 07, 2009–2012.
4. Tag-recapture length increment data.
5. Maturity at length data

4.1.1 Relative abundance estimates from standardised CPUE analyses

The 2013 stock assessment used two sets of standardised CPUE indices: one based on CELR data covering 1990–2001, and another based on PCELR data covering 2002–2013. For both series, standardised CPUE analyses were carried out using Generalised Linear Models (GLMs). A stepwise procedure was used to select predictor variables, with variables entering the model in the order that gave the maximum decrease in the residual deviance. Predictor variables were accepted in the model only if they explained at least 1% of the deviance.

For both the CELR and PCELR data, the Fisher Identification Number (FIN) was used in the standardisations instead of vessel, because the FIN is associated with a permit holder who may employ a suite of grouped vessels, which implies that there could be linkage in the catch rates among vessels operated under a single FIN.

For the CELR data there is ambiguity in what is recorded for estimated daily fishing duration, and it has not been used in past standardisations as a measure of effort, instead the number of divers has been used. However, there is evidence that the fishing duration for a diver changes over time, and because of this a subset of the data was selected for which the recorded fishing duration was less ambiguous. The criteria used to subset the data were: (i) just one diver or (ii) fishing duration ≥ 8 hours and number of divers ≥ 2 . This data subset was used for the CELR standardisation using estimated daily catch and effort as either number of divers or estimated fishing duration (both were offered to the standardisation model).

For the PCELR data the unit of catch was diver catch, with effort as diver duration.

FIN codes were used to select a core group of fishers from the CELR data, with the requirement that there be a minimum of 5 records per year for a minimum of 2 years to qualify for the core fisher group. This retained 80% of the catch over 1990–2001. For the PCELR data the FIN was also used to select a core group of fishers, with the requirement that there be a minimum of 20 records per year for a minimum of 3 years. This retained 89% of the catch over 2002–2013.

For the CELR data year was forced into the model and other predictor variables offered to the model were FIN, statistical area (024, 025, 026, 030), month, fishing duration (as a cubic polynomial), number of divers, and a month:area interaction. For the PCELR data fishing year was forced into the model and variables offered to the model were month, diver key, FIN statistical area, diver duration (third degree polynomial), and diving conditions.

The standardised CPUE from the CELR data have a bump in 1991 but is relatively flat for the first four years, then declines to 40–50% of its initial level (Figure 3-top). The standardised CPUE from the PCELR data show a 60% increase from 2002 to 2013 (Figure 3-bottom).

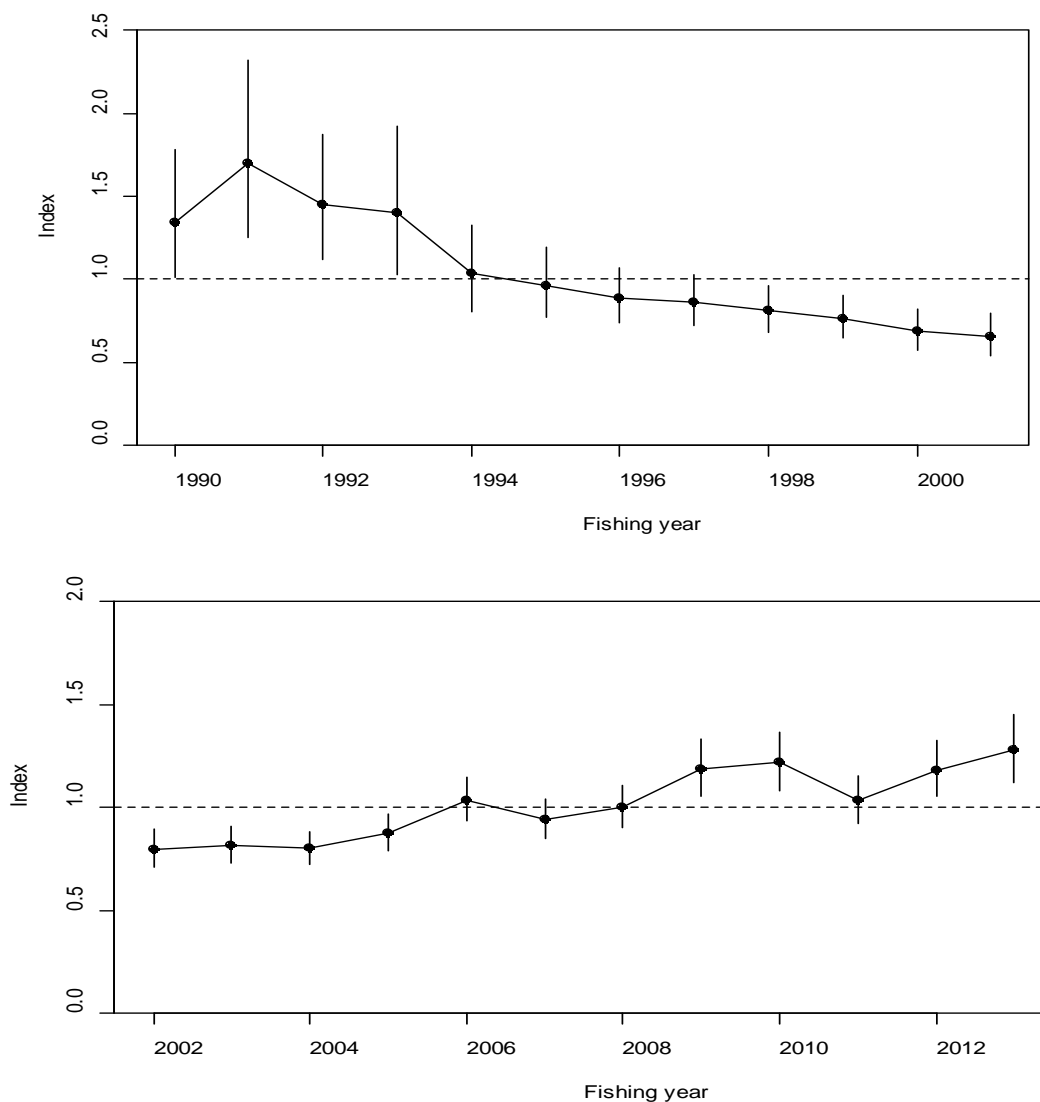

Figure 3: The standardised CPUE indices with 95% confidence intervals for the early CELR/FSU series (top panel) and the recent PCELR series (bottom panel).

4.1.2 Relative abundance estimates from research diver surveys

The relative abundance of puaa in PAU 5B has also been estimated from a number of independent research diver surveys (RDSI) undertaken in various years between 1993 and 2007. The survey strata included Ruggedy, Waituna, Codfish, Pegasus, Lords, and East Cape. These data were not included in the assessment because there is concern that the data are not a reliable index of abundance.

Concerns about the ability of the data collected in the independent Research Dive surveys to reflect relative abundance instigated several reviews in 2009 (Cordue 2009) and 2010 (Haist 2010). The reviews assessed the reliability of the research diver survey index as an index of abundance and whether the RDSI, when used in the puaa stock assessment models, results in model outputs that adequately reflect the status of the stocks. Both reviews suggested that outputs from puaa stock assessments using the RDSI should be treated with caution. For a summary of the conclusions from the reviews refer to the introductory PAU Working Group Report

4.2 Stock assessment methods

The 2013 PAU 5B stock assessment used the same length-based model as the 2012 PAU 5D assessment (Fu 2013). The model was described by Breen *et al.* (2003). PAU 5B was last assessed in 2007 (Breen & Smith 2008) and the most recent assessment is 2013 (Fu 2014 in prep).

The model structure assumed a single sex population residing in a single homogeneous area, with length classes from 70 mm to 170 mm in 2 mm bins. Growth is length-based, without reference to age, mediated through a growth transition matrix that describes the probability of transitions among length class at each time step. Paua enter the model following recruitment and are removed by natural mortality and fishing mortality.

The model simulates the population from 1965 to 2013. Catches were available for 1974-2013 although catches before 1995 must be estimated from the combined PAU 5 catch. Catches were assumed to increase linearly between 1965 and 1973 from 0 to the 1974 catch level. Catches included commercial, recreational, customary, and illegal catch, and all catches occurred within the same time step.

Recruitment was assumed to take place at the beginning of the annual cycle, and length at recruitment was defined by a uniform distribution with a range between 70 and 80 mm. No explicit stock-recruitment relationship was modelled in previous assessments; however, the Shellfish Working Group agreed to use a Beverton-Holt stock-recruitment relationship with steepness (h) of 0.75 for this assessment.

Maturity is not required in the population partition but is necessary for estimating spawning biomass. The model estimated proportions mature from length-at-maturity data. Growth and natural mortalities were also estimated within the model. The model estimated the commercial fishing selectivity, assumed to follow a logistic curve and asymptote at 1. The increase in Minimum Harvest Size between 2006 and 2011 was modelled as an annual shift in fishing selectivity.

The assessment was conducted in several steps. First, the model was fitted to the data with parameters estimated at the mode of their joint posterior distribution (MPD). Next, from the resulting fit, Markov chain-Monte Carlo (MCMC) simulations were made to obtain a large set of samples from the joint posterior distribution. From this set of samples, forward projections were made and an agreed set of biological indicators obtained. Model sensitivity was explored by comparing MPD fits made under alternative model assumptions.

The base case model excluded the RDSI and RDLF data, used the methods recommended by Francis (2011) to determine the relative weights for the proportion-at-length and abundance data, and estimated M assuming a lognormal prior with a mean of 0.1. When the RDSI and RDLF data were included in the model, they had almost no influence on model results. This suggested that the RDSI and RDLF were probably not in conflict with other observations, but this could also be related to their small model weights.

The sensitivity trials included an alternative prior on M , alternative catch history estimates with lower catches between 1985 and 1995, the use of inverse-logistic growth model, and the exclusion of the early or the recent CPUE indices. The sensitivity trials addressed uncertainties associated with various aspects of the input data and model assumptions. MCMCs were carried out for the base case and model run 0.4, which used a uniform prior on M .

The assessment calculates the following quantities from their posterior distributions: the equilibrium spawning stock biomass with recruitment equal to the average recruitment from the period for which recruitment deviation were estimated (B_{0s}), the mid-season spawning and recruited biomass for 2013 (B_{2013} and B_{2013}^r) and for the projection period (B_{proj} and B_{proj}^r). This assessment also reports the following fishery indicators:

- $B\% B_0$ Current or projected spawning biomass as a percentage of B_0
- $B\% B_{msy}$ Current or projected spawning biomass as a percentage of B_{msy}
- $\Pr(B_{proj} > B_{msy})$ Probability that projected spawning biomass is greater than B_{msy}

- $\Pr(B_{proj} > B_{2012})$ Probability that projected spawning biomass is greater than $B_{current}$
- $B\% B_0^r$ Current or projected recruited biomass as a percentage of B_0^r
- $B\% B_{msy}^r$ Current or projected recruited biomass as a percentage of B_{msy}^r
- $\Pr(B_{proj} > B_{msy}^r)$ Probability that projected recruit-sized biomass is greater than B_{msy}^r
- $\Pr(B_{proj} > B_{2012}^r)$ Probability that projected recruit-sized biomass is greater than B_{2012}^r
- $\Pr(B_{proj} > 40\% B_0)$ Probability that projected spawning biomass is greater than 40% B_0
- $\Pr(B_{proj} < 20\% B_0)$ Probability that projected spawning biomass is less than 20% B_0
- $\Pr(B_{proj} < 10\% B_0)$ Probability that projected spawning biomass is less than 10% B_0
- $\Pr(U_{proj} > U_{40\% B_0})$ Probability that projected exploitation rate is greater than $U_{40\% B_0}$

4.3 Stock assessment results

The base case model (0.1) estimated that the unfished spawning stock biomass (B_0) was about 3625 t (3390–3870 t) (Figure 4), and the spawning stock population in 2013 (B_{2013}) was about 44% (36–54%) of B_0 (Table 5). The base case indicated that spawning biomass increased rapidly after 2002 when the stock was at its lowest level. The 3-year model projection, assuming current catch levels and using recruitments re-sampled from the recent model estimates, suggested that the spawning stock abundance will increase to about 48% (0.38–0.61) of B_0 over the next three years (Table 6). The projection also indicated that the probability of the spawning stock biomass being above the target (40% B_0) will increase from about 80% in 2013 to 93% by 2016. The projection assumed the Minimum Harvest Size will remain at 135 mm for the next three years; the projected stock status changed very little if an MHS of 125 mm was assumed

The MCMC simulation started at the MPD parameter values and the traces show good mixing. MCMC chains starting at either higher or lower parameter values also converged after the initial burn-in phase. The base case model estimated an M of 0.12 with a 90% credible interval between 0.11 and 0.14. The midpoint of the commercial fishery selectivity (pre-2006), where selectivity is 50% of the maximum, was estimated to be about 125 mm and the selectivity ogive was very steep. The model estimated an annual shift of about 1.9 mm in selectivity, with a total increase of about 10 mm between 2006 and 2011.

The estimated recruitment deviations showed a period of relatively low recruitment through the 1990s to the early 2000s and the recruitment in recent years (after 2002) has been above the long term average. Exploitation rates peaked around 2002, but have decreased since then. The base case estimated exploitation rate in 2013 to be about 0.11 (0.09–0.14).

When a uniform prior on M was used (MCMC 0.4), the posterior median of M was estimated to be 0.15, and the posterior distribution had a much wider range, with a 90% credible interval between 0.13 and 0.19. This model run produced a more rapid increase in spawning biomass after 2002 with $B_{current}$ estimated to be about 55% (43–73%) of B_0 . Model fits to both CPUE and CSLF changed very little from when the uninformative prior on M was used.

Deterministic B_{msy} was calculated using posterior samples of estimated parameters assuming constant recruitments and a B-H stock-recruitment relationship with a steepness of 0.75. The median of B_{msy} was estimated to be about 28% B_0 for both MCMC 0.1 and 0.4. The corresponding exploitation rate (U_{msy}) was estimated to be 37% for MCMC 0.1 and 67% for MCMC 0.4. The MHS was fixed at 135 mm in the calculation and U_{msy} was sensitive to this value: U_{msy} was estimated to be 22% for MCMC 0.1 and 31% for MCMC 0.4 when an MHS of 125 mm was used. However both MSY and B_{msy} were less sensitive to the values of MHS. Assuming an MHS of 135 mm, $U_{\%40B_0}$ was estimated to be 19% and 30% for MCMC 0.1 and 0.4 respectively.

For a number of reasons (as outlined below) B_{msy} is not currently used as a reference point for managing paua stocks. However, because determining the most suitable target and limit reference points for managing paua stocks is still work in progress, B_{msy} is among the indicators that are being estimated.

There are several reasons why B_{MSY} is not considered a suitable target for management of the paua fishery. First, it assumes a harvest strategy that is unrealistic in that it involves perfect knowledge including perfect catch and biological information and perfect stock assessments (because current biomass must be known exactly in order to calculate target catch), a constant-exploitation management strategy with annual changes in TACC (which are unlikely to happen in New Zealand and not desirable for most stakeholders), and perfect management implementation of the TACC and catch splits with no under- or overruns. Second, it assumes perfect knowledge of the stock-recruit relationship, which is actually very poorly known. Third, it would be very difficult with such a low biomass target to avoid the biomass occasionally falling below 20% B_0 , the default soft limit according to the Harvest Strategy Standard. Thus, the actual target needs to be above this theoretical optimum, but the extent to which it needs to be above has not been determined.

Table 5: Summary of the marginal posterior distributions from the MCMC chain from the base case (Model 0.1), and sensitivity trial (model 0.4). The columns show the median, the 5th and 95th percentiles values observed in the 1000 samples. Biomass is in tonnes.

	MCMC 0.1	MCMC 0.4

4.4 Other factors

The assessment used CPUE as an index of abundance. The assumption that CPUE indexes abundance is questionable. The literature on abalone fisheries suggests that CPUE is problematic for stock assessments because of serial depletion. This can happen when fishers deplete unfished or lightly fished beds and maintain their catch rates by moving to new areas. Thus CPUE stays high while the biomass is actually decreasing. For PAU 5B, the model estimate of stock status was strongly driven by the trend in the recent CPUE indices. It is unknown to what extent the CPUE series tracks stock abundance. The SFWG believed that the increasing trend in recent CPUE series may be credible, corroborating anecdotal evidence from the commercial divers in PAU 5B that the stock has been in good shape in recent years.

Natural mortality is an important productivity parameter. It is often difficult to estimate M reliably within a stock assessment model and the estimate is strongly influenced by the assumed prior. For the paua assessment, the choice of prior has been based on current belief on the plausible range of the natural mortality for paua, and therefore it is reasonable to incorporate available evidence to inform the estimation of M . The sensitivity of model results to the assumptions on M could be assessed through the use of alternative priors.

Another source of uncertainty is the data. The commercial catch is unknown before 1974 and is estimated with uncertainty before 1995. Major differences may exist between the catches we assume and what was actually taken. In addition, non-commercial catch estimates are poorly determined and could be substantially different from what was assumed, although generally non-commercial catches appear to be relatively small compared with commercial catch. The estimate of illegal catch in particular is uncertain.

The model treats the whole of the assessed area of PAU 5B as if it were a single stock with homogeneous biology, habitat and fishing pressures. The model assumes homogeneity in recruitment and natural mortality, and assumes that growth has the same mean and variance throughout. However, it is known that paua in some areas have stunted growth and others are fast-growing.

Heterogeneity in growth can be a problem for this kind of model (Punt 2003). Variation in growth is addressed to some extent by having a stochastic growth transition matrix based on increments observed in several different places; similarly the length frequency data are integrated across samples from many places.

The effect of these factors is likely to make model results optimistic. For instance, if some local stocks are fished very hard and others not fished, recruitment failure can result because of the localized depletion of spawners. Spawners must be close to each other to breed and the dispersal of larvae is unknown and may be limited. Recruitment failure is a common observation in overseas abalone fisheries, so local processes may decrease recruitment, an effect that the current model cannot account for.

Another source of uncertainty is that fishing may cause spatial contraction of populations (Shepherd & Partington 1995), or that some populations become relatively unproductive after initial fishing (Gorfine & Dixon 2000). If this happens, the model will overestimate productivity in the population as a whole. Past recruitments estimated by the model might instead have been the result of serial depletion.

5. STATUS OF THE STOCK

Stock Structure Assumptions

PAU 5B is assumed to be a homogenous stock for purposes of the stock assessment.

• PAU 5B - *Haliotis iris*

Stock Status	
Year of Most Recent Assessment	2014
Assessment Runs Presented	MCMC 0.1 (base case)
Reference Points	Target: 40% B_0 (Default as per HSS) Soft Limit: 20% B_0 (Default as per HSS) Hard Limit: 10% B_0 (Default as per HSS) Overfishing threshold: $U_{40\%B_0}$
Status in relation to Target	B_{2013} was estimated to be 44% B_0 for the base case; About as Likely as Not (40–60%) to be at or above the target
Status in relation to Limits	Very Unlikely (< 10%) to be below the soft and hard limits
Status in Relation to Overfishing	Overfishing is Very Unlikely (< 10%) to be occurring

Historical Stock Status Trajectory and Current Status

Posterior distributions spawning stock biomass as a percentage of the virgin level from MCMC 0.1. The box shows the median of the posterior distribution (horizontal bar), the 25th and 75th percentiles (box), with the whiskers representing the full range of the distribution.

Trajectory of exploitation rate as a ratio $U_{40\%B_0}$ and spawning stock biomass as a ratio of B_0 from the start of assessment period 1965 to 2013 for MCMC 0.1 (base case). The vertical lines at 10%, 20%, 40% B_0 represent the hard limit, the soft limit, and the target respectively. $U_{40\%B_0}$ is the exploitation rate at which the spawning stock biomass would stabilise at 40% B_0 over the long term. Each point on trajectory represents the estimated annual stock status: the value on x axis is the mid-season spawning stock biomass (as a ratio of B_0) and the value on the y axis is the corresponding exploitation rate (as a ratio $U_{40\%B_0}$) for that year. The estimates are based on MCMC medians and the 2012 90% CI is shown by the cross line.

Fishery and Stock Trends

Recent Trend in Biomass or Proxy	Biomass decreased to its lowest level in 2002 but has increased since then.
----------------------------------	---

Recent Trend in Fishing Mortality or Proxy	Exploitation rate peaked in late 1990s and has since declined.
Other Abundance Indices	Standardised CPUE generally declined until the early 2000s, but has shown an increase since then.
Trends in Other Relevant Indicators or Variables	Estimated recruitment was relatively low through the 1990s to the early 2000s and since 2002 has been close to the long term average.

Projections and Prognosis	
Stock Projections or Prognosis	At the current catch level biomass is expected to increase over the next 3 years.
Probability of Current Catch or TACC causing decline below Limits	Results from all models suggest it is Very Unlikely (< 10%) that current catch or TACC will cause a decline below the limits.

Assessment Methodology & Evaluation		
Assessment Type	Full quantitative stock assessment	
Assessment Method	Length based Bayesian model	
Assessment Dates	Latest: 2014	Next: 2017
Overall assessment quality (rank)	1 – High Quality	
Main data inputs (rank)	-Catch history -CPUE indices early series -CPUE indices later series -Commercial sampling length frequencies -Tag recapture data (for growth estimation) -Maturity at length data	1 – High Quality for commercial catch 2 – Medium or Mixed Quality for recreational, customary and illegal as catch histories are not believed to be fully representative of the QMA 2 – Medium or Mixed Quality: not believed to be fully representative of the whole QMA 1 – High Quality 2 – Medium or Mixed Quality: not believed to be fully representative of the whole QMA 1 – High Quality 1 – High Quality
Data not used (rank)	-Research Dive Survey Indices -Research Dive Length Frequencies	3 – Low Quality: not believed to index the stock 3 – Low Quality: not believed to be representative of the entire QMA
Changes to Model Structure and Assumptions	New model	
Major Sources of Uncertainty	<p>-M may not be estimated accurately. There is information in the data that has informed the estimation of M and the prior has also strongly influenced the estimate.</p> <p>- CPUE may not be a reliable index of abundance.</p> <p>-The model treats the whole of the assessed area of PAU 5B as if it were a single stock with homogeneous biology, habitat and fishing pressure.</p> <p>-Any effect of voluntary increases in MHS from 125mm to 135 mm between 2006 and 2011 may not have been adequately captured by the model, which could therefore be underestimating the spawning biomass in recent years.</p>

PAUA (PAU 5D) - Southland / Otago

(*Haliotis iris*)

Paua

1. FISHERY SUMMARY

Before 1995, PAU 5D was part of the PAU 5 QMA, which was introduced into the QMS in 1986 with a TACC of 445 t. As a result of appeals to the Quota Appeal Authority, the TACC increased to 492 t for the 1991–92 fishing year; PAU 5 was then the largest QMA by number of quota holders and TACC. Concerns about the status of the PAU 5 stock led to a voluntary 10% reduction in the TACC in 1994–95. On 1 October 1995, PAU 5 was divided into three QMAs (PAU 5A, PAU 5B, and PAU 5D; see figure above) and the TACC was divided equally among them; the PAU 5D quota was set at 148.98 t.

On 1 October 2002 a TAC of 159 t was set for PAU 5D, comprising a TACC of 114 t, customary and recreational allowances of 3 t and 22 t respectively and an allowance of 20 t for other mortality. The TAC and TACC have been changed since then but customary, recreational and other mortality allowances have remained unchanged (Table 1).

Table 1: Total allowable catches (TAC, t) allowances for customary fishing, recreational fishing, and other sources of mortality (t) and Total Allowable Commercial Catches (TACC, t) declared for PAU 5 and PAU 5D since introduction to the QMS.

Year	TAC	Customary	Recreational	Other mortality	TACC
1986–1991*	-	-	-	-	445
1991–1994*	-	-	-	-	492
1994–1995*	-	-	-	-	442.8
1995–2002	-	-	-	-	148.98
2002–2003	159	3	22	20	114
2003–present	134	3	22	20	89

*PAU 5 TACC figures

1.1 Commercial fishery

The fishing year runs from 1 October to 30 September. On 1 October 2001 it became mandatory to report catch and effort on Paua Catch Effort Landing Returns PCELRs using fine-scale reporting areas that had been developed by the New Zealand Paua Management Company for their voluntary logbook programme (Figure 1). Since 2010 the commercial industry has adopted some voluntary management initiatives which include raising the minimum harvest size for commercial fishers over specific

PAUA (PAU 5D)

statistical reporting areas. The industry has also voluntarily closed, to commercial harvesting, specific areas that are of high importance to recreational paua fishers.

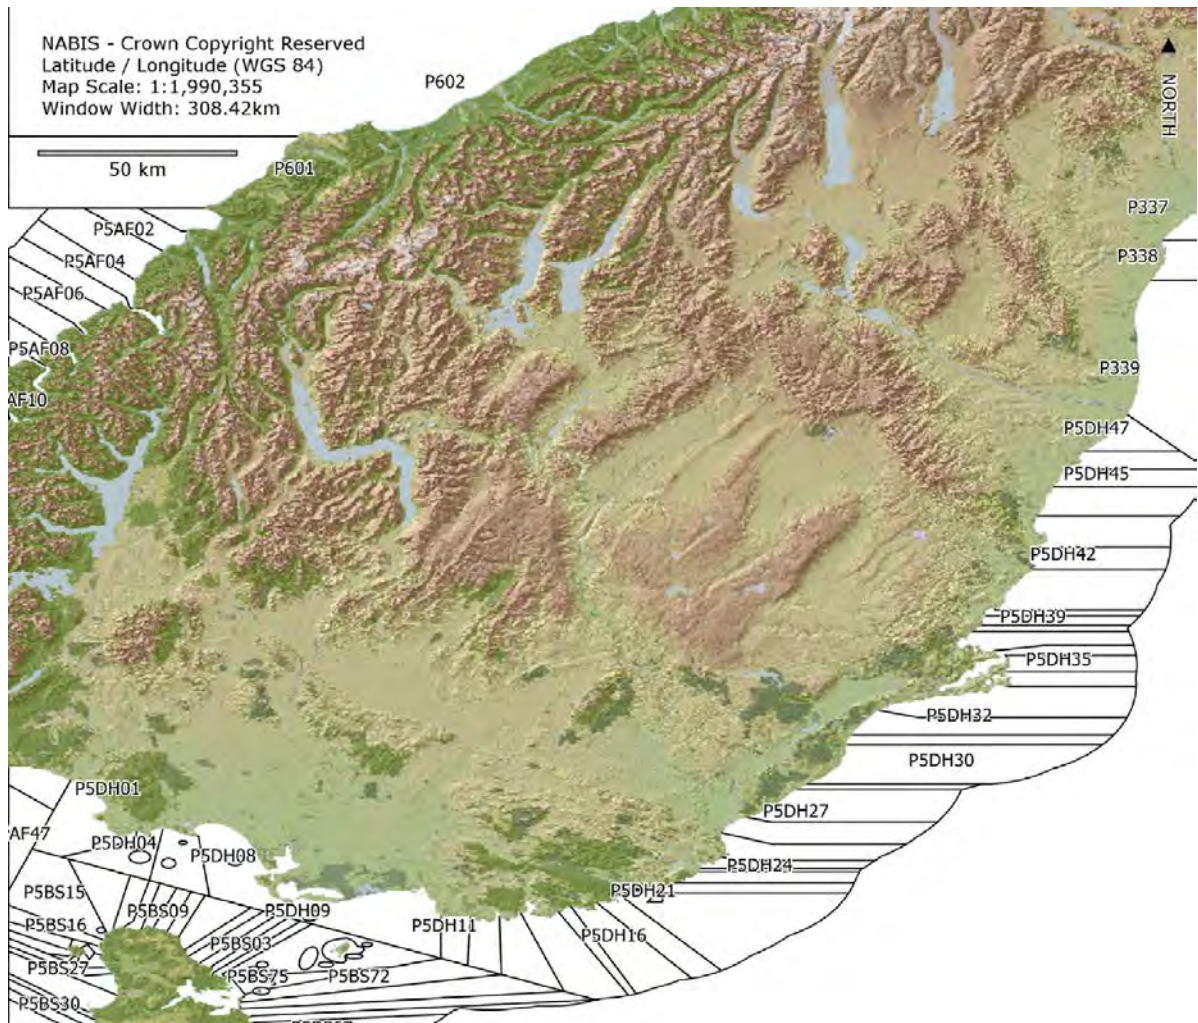

Figure 1: Map of fine scale statistical reporting areas for PAU 5D.

Landings for PAU 5D are shown in Table 2 and Figure 2. Landings for PAU 5 are reported in the introductory PAU Working Group Report.

Table 2: TACC and reported landings (t) of paua in PAU 5D from 1995–96 to the present. Data were estimated from CELR and QMR returns.

Year	Landings	TACC
1995–96	167.42	148.98
1996–97	146.6	148.98
1997–98	146.99	148.98
1998–99	148.78	148.98
1999–00	147.66	148.98
2000–01	149.00	148.98
2001–02	148.74	148.98
2002–03	111.69	114.00
2003–04	88.02	89.00
2004–05	88.82	89.00
2005–06	88.93	89.00
2006–07	88.97	89.00
2007–08	88.98	89.00
2008–09	88.77	89.00
2009–10	89.45	89.00
2010–11	88.70	89.00
2011–12	89.23	89.00
2012–13	87.91	89.00

Figure 2: Historical landings and TACC for PAU 5D from 1995–96 to present. For historical landings in PAU 5 prior to 1995–96 refer to figure 1 and table 1 of the introductory PAU Working Group Report.

1.2 Recreational fisheries

For the purpose of the stock assessment model, the SFWG agreed to assume that the 1974 recreational catch was 2 t increasing linearly to 10 t by 2005. For further information on recreational fisheries refer to the introductory PAU Working Group Report.

1.3 Customary fisheries

For the purpose of the stock assessment model, the SFWG agreed to assume that the customary catch has been constant at 2 t for PAU 5D. For further information on customary fisheries refer to the introductory PAU Working Group Report.

1.4 Illegal catch

For the purpose of the stock assessment model, the SFWG agreed to assume that illegal catches have been constant at 10 t for PAU 5D. For further information on illegal catch refer to the introductory PAU Working Group Report.

1.5 Other sources of mortality

For further information on other sources of mortality refer to the introductory PAU Working Group Report.

2. BIOLOGY

For further information on paua biology refer to the introductory PAU Working Group Report. A summary of biological parameters used in the PAU 5D assessment is presented in Table 3.

3. STOCKS AND AREAS

For further information on stocks and areas refer to the introductory PAU Working Group Report.

PAUA (PAU 5D)

Table 3: Estimates of biological parameters (*H. iris*).

	Estimate	Source
<u>1. Natural mortality (<i>M</i>)</u>		
	0.149 (0.134–0.167)	Median (5–95% range) of posterior estimated by the base case model
<u>2. Weight = $a(\text{length})^b$ (Weight in g, length in mm shell length)</u>		
All	2.99×10^{-5} ^a 3.303 ^b	Schiel & Breen (1991)
<u>3. Size at maturity (shell length)</u>		
50% maturity at 79 mm (78–80)		Median (5–95% range) of posterior estimated by the base case model
95% maturity at 93mm (89–97)		Median (5–95% range) of posterior estimated by the base case model
<u>4. Estimated annual growth increments (both sexes combined)</u>		
at 75 mm	at 120 mm	Median (5–95% range) of posteriors estimated by the base case model
29.3 (26.4–32.5)	7.4 (7.0–7.8)	

4. STOCK ASSESSMENT

The stock assessment was implemented as a length-based Bayesian estimation model, with point estimates of parameters based on the mode of the joint posterior distribution, and uncertainty of model estimates investigated using the marginal posterior distributions generated from Markov chain-Monte Carlo simulations. The most recent stock assessment was conducted for the fishing year ended 30 September 2012. A base case model (5.2 - referred to as the reference model henceforth) was chosen from the assessment. However, most data sets used in the model were from a limited number of locations, and were most likely not representative of the whole QMA therefore; to capture the uncertainty in the stock assessment, three sensitivity runs were conducted: run 5.5 where the early CPUE series was removed, run 6.3 where the growth was fixed high and run 6.5 where the growth was fixed low. All four runs were considered to be equally plausible and showed that it was Very Unlikely the stock will fall below the soft or hard limits over the next three years at current levels of catch and suggested that biomass would increase. However, the four runs differed in their assessment of the status of the stock relative to the target.

4.1 Estimates of fishery parameters and abundance indices

Parameters estimated in the assessment model and their assumed Bayesian priors are summarized in Table 4.

Table 4: A summary of estimated model parameters, lower bound, upper bound, type of prior, (U, uniform; N, normal; LN = lognormal), mean and CV of the prior.

Parameter	Prior	μ	CV	Bounds	
				Lower	Upper
$\ln(R0)$	U	–	–	5	50
<i>M</i> (Natural mortality)	LN	0.1	0.35	0.01	0.5
g_1 (Mean growth at 75 mm)	U	–	–	1	50
g_2 (Mean growth at 120 mm)	U	–	–	0.01	50
ϕ (CV of mean growth)	U	–	–	0.001	1
$\ln(q^1)$ (catchability coefficient of CPUE)	U	–	–	-30	0
$\ln(q^1)$ (catchability coefficient of PCPUE)	U	–	–	-30	0
L_{50} (Length at 50% maturity)	U	–	–	70	145
L_{95-50} (Length between 50% and 95% maturity)	U	–	–	1	50
D_{50} (Length at 50% selectivity for the commercial catch)	U	–	–	70	145
D_{95-50} (Length between 50% and 95% selectivity the commercial catch)	U	–	–	0.01	50
ϵ (Recruitment deviations)	N	0	0.4	-2.3	2.3

The observational data were:

1. A standardised CPUE series covering 1990–2001 based on CELR data.
2. A standardised CPUE series covering 2002–2012 based on PCELR data.
3. A commercial catch sampling length frequency series for 1998, 2002–04, 07, 2009–2012.
4. Tag-recapture length increment data.
5. Maturity at length data

4.1.1 Relative abundance estimates from standardised CPUE analyses

The 2012 stock assessment used two sets of standardised CPUE indices: one based on CELR data covering 1990–2001, and another based on PCELR data covering 2002–2012. For both series, standardised CPUE analyses were carried out using Generalised Linear Models (GLMs). A stepwise procedure was used to select predictor variables, and they were entered into the model in the order that gave the maximum decrease in the Akaike Information Criterion (AIC). Predictor variables were accepted into the model only if they explained at least 1% of the deviance.

For the CELR data, the unit of catch used was the total estimated daily catch for a vessel. Because the diver-hours field on the CELR forms contains errors and ambiguity, the unit of effort used was the total number of diver days (total number of divers on a vessel for a day). The catch effort records from Statistical Areas 025 and 030 before 30 September 1995 were not included in the standardizations as the stock source of the data was unknown. The standardised index is shown in the upper panel of Figure 3.

For the PCELR data, the Fisher Identification Number (FIN) was used in the standardisation instead of vessel, because the FIN is associated with a permit holder who may employ a suite of grouped vessels, which implies that there could be linkage in the catch rates among vessels operated under a single FIN.

The FIN was used to select a core group of records from the CELR data, with the requirement that there be a minimum of 10 records per year for a FIN, for a minimum of two years. This retained 80% of the catch over the period 1990–2001. For the PCELR data the FIN was also used to select a core group of records, with the requirement that there be a minimum of 20 records per year for a minimum of three years. This retained 82% of the catch over the 2002–2012 time period.

The standardisation was done on the natural log of catch per diver day. Variables offered to the model were diver, diving condition, fishing duration, FIN (Fisher identification number), fishing year, month and statistical area; no interactions were included in the model and fishing year was forced to be in the model as an explanatory variable. The standardised index is shown in the lower panel of Figure 3.

The CELR data showed an overall decline in CPUE from 1990 through to the early 2000s. The CPUE estimated from PCELR data s showed a generally increasing trend from 2002 until 2011, with a slight decrease in 2012.

In some circumstances commercial CPUE may not be proportional to abundance because it is possible to maintain catch rates of paua despite a declining biomass. This occurs because paua tend to aggregate and divers move among areas to maximise their catch rates. Apparent stability in CPUE should therefore be interpreted with caution.

PAUA (PAU 5D)

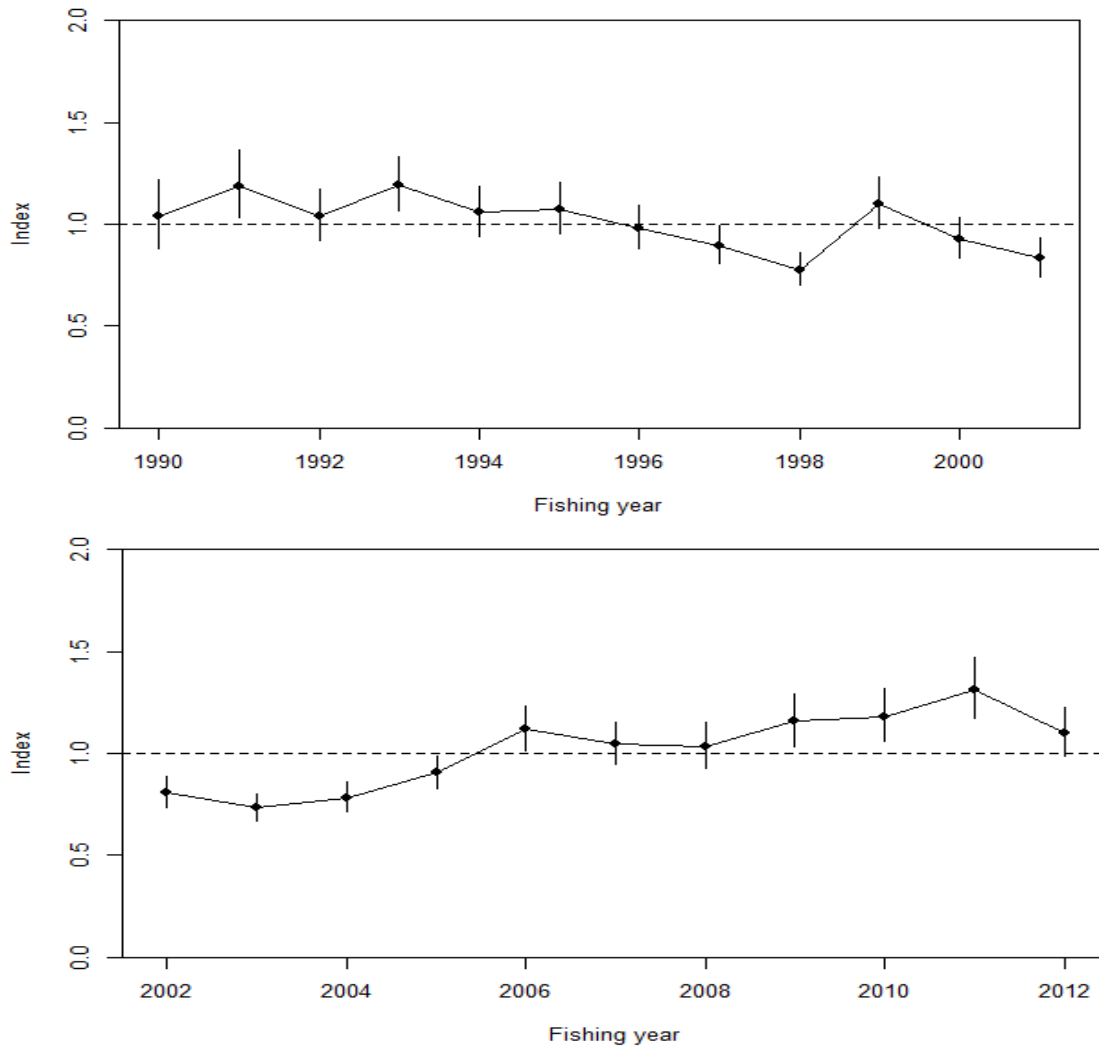

Figure 3: The standardised CPUE indices with 95% confidence intervals for the early CELR series (upper panel) and the recent PCELR series (lower panel).

4.1.2 Relative abundance estimates from research diver surveys

The relative abundance of puaa in PAU 5D has also been estimated from a number of independent research diver surveys (RDSI) undertaken in various years between 1994 and 2004. The survey strata (Catlins East and Catlins West) cover the areas that produced about 25% of the recent catches in PAU 5D. This data was not included in the assessment because there is concern that the data is not a reliable index of abundance and the data is not representative of the whole PAU 5D QMA.

Concerns about the ability of the data collected in the independent Research Dive surveys to reflect relative abundance instigated reviews in 2009 (Cordue 2009) and 2010 (Haist 2010). The reviews assessed the reliability of the research diver survey index as a proxy for abundance and whether the RDSI, when used in the puaa stock assessment models, results in model outputs that adequately reflect the status of the stocks. Both reviews suggested that outputs from puaa stock assessments using the RDSI should be treated with caution. For a summary of the conclusions from the reviews refer to the introductory PAU Working Group Report

4.2 Stock assessment methods

The 2012 PAU 5D stock assessment used the same length-based model used for the 2011 PAU 7 assessment (Fu et al 2012). The model was described by Breen et al (2003). PAU 5D was last assessed in 2006 (Breen & Kim 2007) and the most recent assessment is 2012 (Dan Fu 2013).

The model structure assumed a single sex population residing in a single homogeneous area, with length classes from 70 mm to 170 mm, in groups of 2 mm. Growth is length-based, without reference to age, mediated through a growth transition matrix that describes the probability of each length class changing at each time step. Paua entered the partition following recruitment and were removed by natural mortality and fishing mortality.

The model simulates the population from 1965 to 2012. Catches were available for 1974–2012 although catches before 1995 must be estimated from the combined PAU 5 catch, and were assumed to increase linearly between 1965 and 1973 from 0 to the 1974 catch level. Catches included commercial, recreational, customary, and illegal catch, and all catches occurred within the same time step.

Recruitment was assumed to take place at the beginning of the annual cycle, and length at recruitment was defined by a uniform distribution with a range between 70 and 80 mm. The stock-recruitment relationship is unknown for paua. No explicit stock-recruitment relationship was modelled in previous assessments; however, the Shellfish Working Group agreed to use a Beverton-Holt stock-recruitment relationship with steepness (h) of 0.75 for this assessment.

Maturity is not required in the population partition but is necessary for estimating spawning biomass. The model estimated proportions mature from length-at-maturity data. Growth and natural mortalities were also estimated within the model. The model estimated the commercial fishing selectivity, assumed to follow a logistic curve and to reach an asymptote.

The assessment was conducted in several steps. First, the model was fitted to the data with arbitrary weights on the various data sets. The weights were then iteratively adjusted to produce balanced residuals among the datasets where the standardised deviation of the normalised residuals was close to one for each dataset. The length frequency data were further down-weighted using the method by Francis (2011). The fit obtained is the mode of the joint posterior distribution of parameters (MPD). Next, from the resulting fit, Markov chain-Monte Carlo (MCMC) simulations were made to obtain a large set of samples from the joint posterior distribution. From this set of samples, forward projections were made with a set of agreed indicators obtained. Sensitivity trials were explored by comparing MPD fits made with alternative model assumptions.

The reference model (5.2) excluded the RDSI and RDLF data; fitted the two CPUE series and the CSLF data; estimated growth parameters within the model using an exponential growth curve with the CV fixed at 0.30; estimated M within the model; weighted the CSLF data using the TA1.8 method (Francis 2011). The effects of dropping the tag-recapture data from the model showed that the model is taking a lot of information about growth from the commercial catch length frequency (CSLF) data and it appears that the CSLF data is having the biggest effect on model outcomes.

The sensitivity trials carried out for the MCMC included Run 5.5 where the early CPUE series were dropped, and Run 6.3 and 6.5 where the growth parameters were fixed at values representing either fast growth ($g_1 = 32.5$ and $g_2 = 10$) or slow growth ($g_1 = 24.5$ and $g_2 = 5$) respectively. The sensitivity trials addressed uncertainties in various aspects of the input data.

The assessment calculates the following quantities from their posterior distributions: the equilibrium spawning stock biomass assuming that recruitment is equal to the average recruitment from the period for which recruitment deviation were estimated (B_0), and the mid-season spawning and recruited biomass for 2012 (B_{2012} and B_{2012}^r) and for the projection period (B_{proj} and B_{proj}^r). This assessment also reports the following fishery indicators:

- $B\% B_0$ Current or projected spawning biomass as a percentage of B_0
- $B\% B_{msy}$ Current or projected spawning biomass as a percentage of B_{msy}

PAUA (PAU 5D)

- $\Pr(B_{proj} > B_{msy})$ Probability that projected spawning biomass is greater than B_{msy}
- $\Pr(B_{proj} > B_{2012})$ Probability that projected spawning biomass is greater than $B_{current}$
- $B\% B_0^r$ Current or projected recruited biomass as a percentage of B_0^r
- $B\% B_{msy}^r$ Current or projected recruited biomass as a percentage of B_{msy}^r
- $\Pr(B_{proj} > B_{msy}^r)$ Probability that projected recruit-sized biomass is greater than B_{msy}^r
- $\Pr(B_{proj} > B_{2012}^r)$ Probability that projected recruit-sized biomass is greater than B_{2012}^r
- $\Pr(B_{proj} > 40\% B_0)$ Probability that projected spawning biomass is greater than 40% B_0
- $\Pr(B_{proj} < 20\% B_0)$ Probability that projected spawning biomass is less than 20% B_0
- $\Pr(B_{proj} < 10\% B_0)$ Probability that projected spawning biomass is less than 10% B_0
- $\Pr(U_{proj} > U_{40\% B_0})$ Probability that projected exploitation rate is greater than $U_{40\% B_0}$

4.3 Stock assessment results

The reference case model (5.2) estimated that the unfished spawning stock biomass (B_0) was about 2285 t (2099–2487 t) (Figure 4), and the spawning stock population in 2012 (B_{2012}) was about 35% (28–44%) of B_0 (Table 5). The model projection made for three years assuming current catch levels and using recruitments re-sampled from the recent model estimates, suggested that the spawning stock abundance will increase to about 39% (27–54%) of B_0 over the next three years (Table 6). The projection also indicated that the probability of the spawning stock biomass being above the target (40% B_0) will increase from about 15% in 2012 to 43% by 2015.

The reference case model appeared to fit most data well, and there is no obvious indication of lack of fit. Natural mortality was estimated to be about 0.15. Estimated commercial catch selectivity was very steep with the 50% selectivity (D_{50}) being close to 125 mm. The estimated recruitment was high in the mid-1990s and early 2000s. The estimated exploitation rate peaked in 2001 and since then has been decreasing, with the U_{2012} estimated at 21% and the exploitation rate required to achieve the target of 40% B_0 ($U_{40\% B_0}$) over the long term was 16%.

When the early CPUE series was dropped (Run 5.5), the model estimated the unfished spawning stock biomass (B_0) to be about 2535 t (2335–2742 t) and showed a much steeper decline in biomass between 1990 and 2001 (Figure 5). Estimated B_{2012} was about 26% (20–35%) of B_0 , current exploitation rate was 26% and $U_{40\% B_0}$ was 13% (Table 5). The model projections (Table 7) suggested an increase in biomass over the next three years, with a 3% probability of being above the target of 40% B_0 by 2015.

When the growth parameters were fixed at higher values (Run 6.3), the unfished spawning stock biomass (B_0) was estimated at 1987 t (1821–2158 t) (Figure 4). B_{2012} was 22% (19–27%) of B_0 , U_{2012} was 35% and $U_{40\% B_0}$ was 16% (Table 5). The model projections (Table 8) suggested an increase in biomass over the next three years, with a 2% probability of being above the target by 2015.

When the growth parameters were fixed at lower values (Run 6.5), the unfished spawning stock biomass (B_0) was estimated at 3375 t (3053–3841) (Figure 4). B_{2012} was estimated to be 60% (50–72%) of B_0 , U_{2012} was 8% and $U_{40\% B_0}$ was 16% (Table 5). The model projections (Table 9) suggest that the stock biomass is currently above target and will increase over the next three years.

Projections made from all four assessment runs presented suggest that the stock is Very Unlikely (less than 10%) to fall below the soft or hard limits at the current level of catch.

Deterministic B_{msy} was also calculated in the 2012 assessment with B_{msy} estimated at 624 t, 704 t, 556 t and 912 t for the 5.2, 5.5, 6.3 and 6.5 assessment runs respectively (Table 5). The corresponding exploitation rates (U_{msy}) were estimated at 26%, 20%, 25% and 31% (Table 5). Projections from the

different assessment runs estimated the probability of the biomass in 2015 being above B_{msy} to be 40–100% (Tables 6, 7, 8 and 9).

For a number of reasons (as outlined below) B_{msy} is not currently used as a reference point for managing paua stocks. However, because determining the most suitable target and limit reference points for managing paua stocks is still work in progress, B_{msy} is among the indicators that are being estimated.

There are several reasons why B_{msy} is not considered a suitable target for management of the paua fishery. First, it assumes a harvest strategy that is unrealistic in that it involves perfect knowledge including perfect catch and biological information and perfect stock assessments (because current biomass must be known exactly in order to calculate target catch), a constant-exploitation management strategy with annual changes in TACC (which are unlikely to happen in New Zealand and not desirable for most stakeholders), and perfect management implementation of the TACC and catch splits with no under- or overruns. Second, it assumes perfect knowledge of the stock-recruit relationship, which is actually very poorly known. Third, it would be very difficult with such a low biomass target to avoid the biomass occasionally falling below 20% B_0 , the default soft limit according to the Harvest Strategy Standard. Thus, the actual target needs to be above this theoretical optimum; but the extent to which it needs to be above has not been determined.

Table 5: Summary of the marginal posterior distributions from the MCMC chain from Run 5.2 (base case), and sensitivity trials Run 5.5 (no early CPUE), 6.3 (fast growth), and 6.5 (slow growth). The columns show the median, the 5th and 95th percentiles values observed in the 1000 samples. Biomass is in tonnes.

	MCMC 5.2	MCMC 5.5	MCMC 6.3	MCMC 6.5

4.4 Other factors

The assessment used the CPUE as an index of abundance. The assumption that CPUE indexes abundance is questionable. The literature on abalone fisheries suggests that CPUE is difficult to use in abalone stock assessments because of serial depletion. This can happen when fishers can deplete unfished or lightly fished beds and maintain their catch rates by moving to new unfished beds, thus CPUE stays high while the biomass is actually decreasing. For PAU 5D, there is some additional uncertainty associated with the early CPUE: the standardisations suggested that there were different trends among statistical areas (the overall indices were unlikely to track abundance as the weights for each area cannot be easily determined); the level of decline in the CPUE indices appeared too small for the early stage of the fishery. The model results were sensitive to the inclusion/exclusion of the early CPUE indices.

Another source of uncertainty is the data. The commercial catch is unknown before 1974 and is estimated with uncertainty before 1995. Major differences may exist between the catches we assume and what was actually taken. In addition, non-commercial catch estimates are poorly determined and could be substantially different from what was assumed, although generally non-commercial catches appear to be relatively small compared with commercial catch. The estimate of illegal catch in particular is uncertain.

Tag-recapture data were mainly from the Catlin areas and therefore may not reflect fully the average growth in the population. Model estimates of stock status were sensitive to the range of possible growth values examined. Maturity data were collected from Catlin West and may not represent the population either. Length frequency data collected from the commercial catch may not represent the commercial catch with high precision. The research diver survey covered only the Catlin Area, the abundance indices and associated length frequencies were unlikely to represent the trend in the whole population.

The model treats the whole of the assessed area of PAU 5D as if it were a single stock with homogeneous biology, habitat and fishing pressures. The model assumes homogeneity in recruitment and natural mortality, and assumes that growth has the same mean and variance throughout. However it is known that paua in some areas have stunted growth, and others are fast-growing.

PAUA (PAU 5D)

Heterogeneity in growth can be a problem for this kind of model (Punt 2003). Variation in growth is addressed to some extent by having a stochastic growth transition matrix based on increments observed in several different places; similarly the length frequency data are integrated across samples from many places.

The effect of these factors is likely to make model results optimistic. For instance, if some local stocks are fished very hard and others not fished, recruitment failure can result because of the depletion of spawners, because spawners must breed close to each other and the dispersal of larvae is unknown and may be limited. Recruitment failure is a common observation in overseas abalone fisheries, so local processes may decrease recruitment, an effect that the current model cannot account for.

Another source of uncertainty is that fishing may cause spatial contraction of populations (Shepherd & Partington 1995), or that some populations become relatively unproductive after initial fishing (Gorfine & Dixon 2000). If this happens, the model will overestimate productivity in the population as a whole. Past recruitments estimated by the model might instead have been the result of serial depletion.

5. STATUS OF THE STOCK

Stock Structure Assumptions

PAU 5D is assumed in the model to be a discrete and homogenous stock

- **PAU 5D - *Haliotis iris***

Stock Status	
Year of Most Recent Assessment	2013
Assessment Runs Presented	Reference case MCMC (5.2) Early CPUE data excluded MCMC (5.5) Growth fixed high MCMC (6.3) Growth fixed low MCMC (6.5) All assessment runs are considered equally valid
Reference Points	Interim Target: 40% B_0 (Default as per HSS) Soft Limit: 20% B_0 (Default as per HSS) Hard Limit: 10% B_0 (Default as per HSS) Overfishing threshold: $U_{40\%B_0}$
Status in relation to Target	B_{2012} is estimated to be at 35%, 26% and 22% B_0 for assessment runs 5.2, 5.5 and 6.3 respectively. Run 6.5 estimates B_{2012} to be 60% B_0 .
Status in relation to Limits	The stock is Very Unlikely (< 10%) to be below the soft and hard limits
Status in Relation to Overfishing	Assessment runs 5.2, 5.5 and 6.3 suggest that a reduction in exploitation rate may achieve the interim target of 40% B_0 more quickly. Run 6.5 suggests that the current exploitation rate meets and exceeds the target.

Historical Stock Status Trajectory and Current Status

Trajectory of exploitation rate as a ratio of $U_{\%40B0}$ and spawning stock biomass as a ratio of B_0 from the start of assessment period 1965 to 2012 for MCMC 5.2 (base case), 5.5 (no early CPUE), 6.3 (fast growth), and 6.5 (slow growth). The vertical lines at 10%, 20%, 40% B_0 represent the hard limit, the soft limit, and the target respectively. $U_{\%40B0}$ is the exploitation rate at which the spawning stock biomass would stabilise at 40% B_0 over the long term. Each point on trajectory represents the estimated annual stock status: the value on the x axis is the mid-season spawning stock biomass (as a ratio of B_0) and the value on the y axis is the corresponding exploitation rate (as a ratio $U_{\%40B0}$) for that year. For all the models, the trajectory started in year 1965 when the SSB is close to B_0 and the exploitation rate is close to 0. The estimates are based on MCMC median and the 2012 90% CI is shown by the cross line. [Continued on next page].

Trajectory of exploitation rate as a ratio of U_{40B_0} and spawning stock biomass as a ratio of B_0 from the start of assessment period 1965 to 2012 for MCMC 5.2 (base case), 5.5 (no early CPUE), 6.3 (fast growth), and 6.5 (slow growth). The vertical lines at 10%, 20%, 40% B_0 represent the hard limit, the soft limit, and the target respectively. U_{40B_0} is the exploitation rate at which the spawning stock biomass would stabilise at 40% B_0 over the long term. Each point on trajectory represents the estimated annual stock status: the value on the x axis is the mid-season spawning stock biomass (as a ratio of B_0) and the value on the y axis is the corresponding exploitation rate (as a ratio U_{40B_0}) for that year. For all the models, the trajectory started in year 1965 when the SSB is close to B_0 and the exploitation rate is close to 0. The estimates are based on MCMC median and the 2012 90% CI is shown by the cross line.

Fishery and Stock Trends

Recent Trend in Biomass or Proxy	Biomass increased from about 2002 to 2008 and has since been stable.
Recent Trend in Fishing Mortality or Proxy	Exploitation rate peaked in 2002 and has since declined.

Other Abundance Indices	Standardised CPUE generally declined until the early 2000s, but has shown a gradual increase since then.
Trends in Other Relevant Indicators or Variables	Estimated recruitment was relatively low in the late 1990s, and high in the early 2000s, and since 2004 has been close to long term average.

Projections and Prognosis	
Stock Projections or Prognosis	At the current catch level biomass is expected to increase over the next 3 years.
Probability of Current Catch or TACC causing decline below Limits	Results from all models assessment runs presented suggest it is very unlikely (<10%) that current catch or TACC will cause a decline below the limits.

Assessment Methodology and Evaluation		
Assessment Type	1- Full Quantitative Stock Assessment	
Assessment Method	Length based Bayesian model	
Assessment Dates	Latest: 2013	Next: 2016
Overall assessment quality (rank)	1 – High Quality	
Main data inputs (rank)	<ul style="list-style-type: none"> - Catch History - CPUE Indices early series - CPUE Indices later series - Commercial sampling length frequencies - Tag recapture data - Maturity at length data 	<ul style="list-style-type: none"> 2 – Medium or Mixed Quality: not believed to be fully representative of catch in the QMA 2 – Medium or Mixed Quality: not believed to be fully representative of CPUE in the QMA. 1– High Quality 2 – Medium or Mixed Quality: not believed to be representative of the whole QMA 2 – Medium or Mixed Quality: not believed to be representative of the whole QMA 2 – Medium or Mixed Quality: not believed to be representative of the whole QMA
Data not used (rank)	<ul style="list-style-type: none"> - Research Dive survey indices - Research Dive length frequencies 	<ul style="list-style-type: none"> 3 – Low Quality: not believed to be a reliable indicator of abundance in the whole QMA 3 – Low Quality: not believed to be a reliable indicator of length frequency in the whole QMA
Changes to Model Structure and Assumptions	-	
Major Sources of Uncertainty	<ul style="list-style-type: none"> - Growth data were limited and may not be representative of growth within the whole QMA. This was explored through models with alternative growth assumptions, which show the high degree of uncertainty about current stock status associated with uncertainty about growth. - Assuming CPUE is a reliable index of abundance. - The model treats the whole of the assessed area of PAU 5D as if it 	

	<p>were a single stock with homogeneous biology, habitat and fishing pressures.</p> <p>- Any effect of voluntary increases in MHS from 125mm to 132mm over the last five years may not have been adequately captured by the model, which could therefore be underestimating the spawning biomass in recent years.</p>

PAUA (PAU 7) – Marlborough

(Haliotis iris)

Paua

1. FISHERY SUMMARY

PAU 7 was introduced into the Quota Management System in 1986–87 with a TACC of 250 t. As a result of appeals to the Quota Appeal Authority the TACC increased to 267.48 t by 1989. On 1st October 2001 a TAC of 273.73 t was set with a TACC of 240.73 t, customary and recreational allowances of 15 t each and an allowance of 3 t for other mortality. On 1 October 2002 the TAC was reduced to 220.24 t and the TACC was set at 187.24 t. No changes were made to the customary, recreational or other mortality allowances (Table 1).

Table 1. Total allowable catches (TAC, t) allowances for customary fishing, recreational fishing, and other sources of mortality (t) and Total Allowable Commercial Catches (TACC, t) declared for PAU 7 since introduction into the QMS.

Year	TAC	Customary	Recreational	Other mortality	TACC
1986–89	-	-	-	-	250.00
1989–2001	-	-	-	-	267.48
2001–02	273.73	15	15	3	240.73
2002–present	220.24	15	15	3	187.24

1.1 Commercial fisheries

The fishing year runs from 1 October to 30 September. In 2001–02 concerns about the status of the PAU 7 fishery led to a decision by the commercial sector to voluntarily shelve 20% of the TACC for that fishing year. From the 2003–04 to the 2006–07 fishing years the industry proposed to shelve 15% of the TACC. The proposal met with varying success, with less than 15% of the ACE being shelved in three of the four years.

On 1 October 2001 it became mandatory to report catch and effort on PCELRs using fine-scale reporting areas that had been developed by the New Zealand Paua Management Company for their voluntary logbook programme (Figure 1). Reported landings and TACCs for PAU 7 are shown in Table 2 and Figure 2.

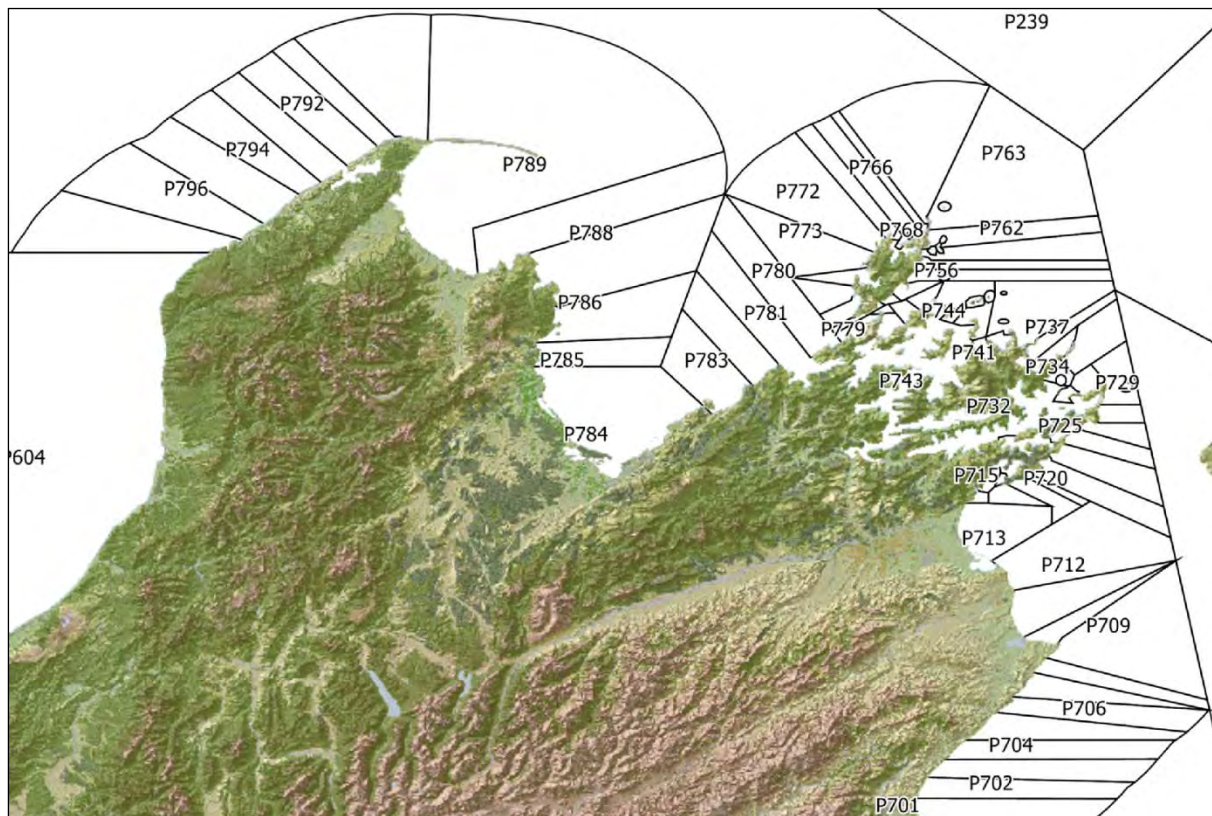

Figure 1: Map of fine scale statistical reporting areas for PAU 7.

Table 2: Reported Landings and TACC in PAU 7 from 1983–84 to the present. The last column shows the TACC after shelving has been accounted for.

Year	Landings (kg)	TACC (t)	After shelving	Year	Landings (kg)	TACC (t)	After shelving
1973–74	147 440	-	-	1993–94	255 472	266.17	266.17

* Voluntary shelving

1.2 Recreational fisheries

For the purpose of the stock assessment, the Shellfish Working Group (SFWG) agreed to assume that recreational catch was 5 t in 1974 and that it increased linearly to 15 t in 2000, and then remained at 15 t. For further information on recreational fisheries refer to the introductory PAU Working Group Report.

Figure 2: Historical landings and TACC for PAU 7 from 1986–87 to present. QMS data from 1986–present.

1.3 Customary fisheries

For the purpose of the stock assessment the SFWG agreed to assume that customary catch was 4 t in 1974, increasing linearly to 10 t between 1974 and 2000, and then remaining at 10 t. For further information on customary fisheries refer to the introductory PAU Working Group Report.

1.4 Illegal catch

For the purpose of the stock assessment the SFWG agreed to assume that illegal catch was 1 t in 1974 and that it increased linearly to 15 t between 1974 and 2000, remaining at 15 t from 2000 through to 2005, and then decreasing linearly to 7.5 t in 2008. For projections the Working Group agreed to assume that illegal catch would remain at 7.5 t. For further information on illegal catch refer to the introductory PAU Working Group Report.

1.5 Other sources of mortality

The Working Group agreed that handling mortality would not be factored into the model. For further information on other sources of mortality refer to the introductory PAU Working Group Report.

2. BIOLOGY

For further information on paua biology refer to the introductory PAU Working Group Report. A summary of biological parameters used in the PAU 7 stock assessment is presented in Table 3.

Table 3: Estimates of biological parameters (*H. iris*).

	Estimate	Source
1. Natural mortality (<i>M</i>)		
All	0.02–0.25	Sainsbury (1982)
PAU 7	0.14 (0.13–0.15) Median (5%–95% C.L.)	estimated by the assessment model
2. Weight = a (length) ^b (weight in g, shell length in mm)		
	a = 2.59E–08 b = 3.322	Schiel & Breen (1991)
3. Size at maturity (shell length)		
50% mature	90.7(89.9–91.5) mm Median (5%–95% C.L.)	estimated by the assessment model
length at 95% mature - 50% mature	11.6(9.6–13.4) mm Median (5%–95% C.L.)	estimated by the assessment model
4. Exponential growth parameters (both sexes combined)		
g_{75}	25.8(23.0–28.7) mm Median (5%–95% C.L.)	estimated by the assessment model: growth increment of animal with initial length of 75 mm.
g_{120}	5.5 (5.1–5.8) mm Median (5%–95% C.L.)	estimated by the model: growth increment of animal with initial length of 120 mm.

3. STOCKS AND AREAS

For further information on stocks and areas refer to the introductory PAU Working Group Report.

4. STOCK ASSESSMENT

The stock assessment is implemented as a length-based Bayesian estimation model, with point estimates of parameters based on the mode of the joint posterior distribution, and uncertainty of model estimates investigated using the marginal posterior distributions generated from Markov chain-Monte Carlo simulations. The 2011 assessment was restricted to Statistical Areas 017 and 038 which includes most (over 90%) of the recent catch.

4.1 Estimates of fishery parameters and abundance indices

Parameters estimated in the assessment model and their assumed Bayesian priors are summarized in Table 4.

Table 4: A summary of estimated model parameters, lower bound, upper bound, type of prior, (*U*, uniform; *N*, normal; *LN* = lognormal), mean and CV of the prior.

Parameter	Prior	μ	C.V.	Bounds	
				Lower	Upper
$\ln(R0)$	<i>U</i>	–	–	5	50
<i>M</i> (Natural mortality)	<i>LN</i>	0.1	0.35	0.01	0.5
g_1 (Mean growth at 75 mm)	<i>U</i>	–	–	1	50
g_2 (Mean growth at 75 mm)	<i>U</i>	–	–	0.01	50
ϕ (cv of mean growth)	<i>U</i>	–	–	0.001	1
$\ln(q^j)$ (catchability coefficient of CPUE)	<i>U</i>	–	–	-30	0
$\ln(q^j)$ (catchability coefficient of PCPUE)	<i>U</i>	–	–	-30	0
$\ln(q^k)$ (catchability coefficient of RDSI)	<i>U</i>	–	–	-30	0
L_{50} (Length at 50% maturity)	<i>U</i>	–	–	70	145
L_{95-50} (Length between 50% and 95% maturity)	<i>U</i>	–	–	1	50
T_{50} (Length at 50% selectivity for the diver survey)	<i>U</i>	–	–	70	125
T_{95-50} (Length between 50% and 95% selectivity for the diver survey)	<i>U</i>	–	–	0.001	50
D_{50} (Length at 50% selectivity for the diver survey)	<i>U</i>	–	–	70	145
D_{95-50} (Length between 50% and 95% selectivity for the diver survey)	<i>U</i>	–	–	0.01	50
ϵ (Recruitment deviations)	<i>N</i>	0	0.4	-2.3	2.3
h (CPUE shape parameter)	<i>U</i>	–	–	0.01	2

The observational data were:

1. A standardised CPUE series covering 1983–2001 based on FSU/CELR data.
2. A standardised CPUE series covering 2002–2011 based on PCELR data.
3. A standardised research diver survey index (RDSI).
4. A research diver survey proportions-at-lengths series (RDLF).
5. A commercial catch sampling length frequency series (CSLF).
6. Tag-recapture length increment data.
7. Maturity at length data.

4.1.1 Relative abundance estimates from standardised CPUE analyses

The 2011 stock assessment used two sets of standardised CPUE indices: one based on FSU/CELR data covering 1983–2001, and another based on PCELR data covering 2002–2011. For both series, standardised catch per unit effort (CPUE) analyses were carried out using Generalised Linear Models (GLMs). A stepwise procedure was used to select predictor variables, and they were entered into the model in the order that gave the maximum decrease in the Akaike Information Criterion (AIC). Predictor variables were accepted into the model only if they explained at least 1% of the deviance.

The standardised index of FSU/CELR series from the 2005 assessment is re-presented here, as the SFWG agreed that it was not necessary to update this series. The unit of catch used was the total estimated daily catch for a vessel. As the diver-hours field on the CELR forms contains a high number of errors, the unit of effort used was the total number of diver days (total number of divers on a vessel for a day). Records were restricted to those from vessels that fished the top 75% of catch in any given year, and from areas 017 and 038. The standardised index is shown in the left panel of Figure 3.

PCELR data were extracted in October 2011 for the time frame 1 October 2001 to 30 September 2011. The Shellfish Working Group suggested that the Fisher Identification Number (FIN) be used in the standardisation instead of vessel. The reason for this is that the FIN is associated with a permit holder who may employ a suite of grouped vessels, which implies that there could be linkage in the catch rates among vessels operated under a single FIN. It was decided to use criteria which specified a minimum number of records (PCELRs and CELRs) per year for a minimum number of years for selecting FIN permit holders for the model. The selected criteria were at least 40 records per year for a minimum of four years. This reduced the number of FIN permit holders from 72 to 20, but retained 76% of the original catch over 2002–2011.

To ensure that there were sufficient data to estimate fine scale statistical area and diver effects in the standardisation, only those fine scale statistical areas and divers with at least 10 diver days were retained. This dropped the number of fine scale statistical areas from 54 to 45, and the number of divers from 379 to 82 (51% of divers have just one dive-day).

The standardisation was done on the natural log of catch per diver day. Variables offered to the model were diver, diving condition, fishing duration FIN (Fisher identification number), fishing year, month and statistical area; no interactions were included in the model and fishing year was forced to be in the model as an explanatory variable. The standardised index is shown in the right panel of Figure 3.

Figure 3: The standardised CPUE indices with 95% confidence intervals for the early CELR/FSU series (left) and the recent PCELR series (right).

4.1.2 Relative abundance estimates from research diver surveys

The relative abundance of paua in PAU 7 was also estimated from a number of independent research diver surveys (RDSI) undertaken in various years between 1992 and 2005. Concerns about the reliability of these data to estimate relative abundance instigated reviews in 2009 (Cordue 2009) and 2010 (Haist 2010). The reviews assessed i) the reliability of the research diver survey index as a proxy for abundance and ii) whether the RDSI, when used in the paua stock assessment models, results in model outputs that adequately reflect the status of the stocks. Both reviews suggested that outputs from paua stock assessments using the RDSI should be treated with caution. For a summary of the conclusions from the reviews refer to the introductory PAU Working Group Report. Relative abundance estimates from research diver surveys are shown in Figure 4.

Figure 4: The standardised RDSI from the negative-binomial GLM models fitted to paired diver counts for surveys in Statistical Areas 017 and 038 within PAU 7.

4.2 Stock assessment methods

The 2012 PAU 7 stock assessment (Fu 2012, Fu et al 2012) used the length-based model first implemented in 1999 for PAU 5B (Breen et al 2000 and revised for subsequent assessments in PAU 7 (Andrew et al 2000, Breen & Kim 2003, Breen & Kim 2005 and Fu 2012). The model is described in Breen et al (2003).

The model structure assumes a single sex population residing in a single homogeneous area, with length classes from 70 mm to 170 mm, in groups of 2 mm. Growth is length-based, without reference to age, mediated through a growth transition matrix that describes the probability of each length class changing at each time step. Paua enter the partition following recruitment and are removed by natural mortality and fishing mortality. The assessment addresses only Areas 017 and 038 within PAU 7. These areas have supported most (more than 90%) of the catch until recently, and all of the available data originate from these two areas, but the relationship between this subset of PAU 7 and the remainder of PAU 7 is uncertain.

The model simulates the population dynamics from 1965 to 2011. Catches were available for 1974–2011, and were assumed to increase linearly between 1965 and 1973 from 0 to the 1974 catch level. Catches included commercial, recreational, customary, and illegal catch, and all catches occurred within the same time step.

Recruitment was assumed to take place at the beginning of the annual cycle, and length at recruitment was defined by a uniform distribution with a range between 70 and 80 mm. The stock-recruitment relationship is unknown for paua. A relationship may exist on small scales, but not be apparent when large-scale data are modelled (Breen et al 2003). No explicit stock-recruitment relationship was modelled in previous assessments; however, the SFWG agreed to use a Beverton-Holt stock-recruitment relationship with steepness (h) of 0.75 for this assessment.

Maturity is not required in the population partition. The model estimated proportions mature with the inclusion of length-at-maturity data. Growth and natural mortalities were also estimated within the model.

The models used two selectivities: the commercial fishing selectivity and research diver survey selectivity, both assumed to follow a logistic curve and to reach an asymptote.

The assessment was conducted in several steps. First, the model was fitted to the data with arbitrary weights on the various data sets. The weights were then iteratively adjusted to produce balanced residuals among the datasets where the standardised deviation of the normalised residuals was close to one for each dataset. The fit obtained is the mode of the joint posterior distribution of parameters (MPD). Next, from the resulting fit, Markov chain-Monte Carlo (MCMC) simulations were made to obtain a large set of samples from the joint posterior distribution. From this set of samples, forward projections were made with a set of agreed indicators obtained. Sensitivity trials were explored by comparing MPD fits made with alternative model assumptions.

A base case model (1.0) was chosen by the SFWG for the assessment: the tag-recapture data from all areas (except for D’Urville) were included, growth parameters were estimated within the model using an exponential growth curve, the weighting of the proportion-at-length data was determined using the TA1.8 method (Francis 2011), and maturity data from Northern faces were excluded. The base case model also assumed a steepness of 0.75 for the stock-recruitment relationship and estimated the CPUE shape parameter. The base case and sensitivities are summarised in Table 5.

The assessment reported:

- B_0 (the equilibrium spawning stock biomass assuming that recruitment is equal to the average recruitment from the period for which recruitment deviation were estimated).
- The mid-season spawning and recruited biomass for 2011 ($B_{current}$ and $B^r_{current}$), and for the projected period (B_{proj} and B^r_{proj}), and from a reference period, 1985–87. The latter was a period that had been previously chosen because the biomass was relatively stable. The means of values from the three years were called B_{ref} and B^r_{ref} for spawning and legal biomass respectively. Legal biomass is the biomass of paua above the legal size limit (currently 125 mm).
- % B_0 Ratio of current and projected spawning biomass to B_0 .
- % B_{ref} Ratio of current and projected spawning biomass to B_{ref} .
- $\Pr(>B_{ref})$ Probabilities that current and projected spawning biomass greater than B_{ref} .
- $\Pr(>B_{current})$ Probabilities that projected spawning biomass greater than $B_{current}$.
- $\Pr(<20\% B_0)$ Probabilities that projected spawning biomass is less than 20% B_0 .
- $\Pr(<10\% B_0)$ Probabilities that projected spawning biomass is less than 10% B_0 .
- % B^r_0 Ratio of current and projected legal biomass to B^r_0 .
- % B^r_{ref} Ratio of current and projected legal biomass to B^r_{ref} .
- $\Pr(>B^r_{ref})$ Probabilities that current and projected legal biomass greater than B^r_{ref} .
- $\Pr(>B^r_{current})$ Probabilities that projected legal biomass greater than $B^r_{current}$.

Recruitments for projections were obtained by randomly re-sampling model estimates from 1996 to 2006. Projections were run at four different levels of catch: the current TACC, and reductions of 10%, 15% and 20%.

4.2.1 Stock assessment results

Current estimates from the base case suggested that spawning stock population in 2011 ($B_{current}$) was about 22% (19–26%) of the unfished level (B_0), and vulnerable biomass ($B^r_{current}$) was about 10% (8–12%) of the initial state (B^r_0) (Figure 5, Table 6). Model projections made for three years, assuming current catch levels and using recruitments re-sampled from the recent model estimates, suggested that the spawning stock biomass will slightly increase to about 23.4% (17–32%) B_0 over the next three years (Table 7). Projections made with alternative catch levels showed that the spawning stock biomass will increase to about 24.4%, 25.0%, and 25.5% B_0 respectively, if the current TACC was to be reduced by 10%, 15% and 20% respectively (Table 7).

Table 5: Summary descriptions for base case and sensitivity model runs.

Model runs	Descriptions
0.0 (Initial model)	Iterative reweighting, assumed h of 0.75 and U^{max} of 0.8, estimated h
1.0 (Base case)	TA1.8 weighting method, assumed h of 0.75 and U^{max} of 0.8, estimated h
1.1	1.0, but fixed CPUE shape parameter (??) at 1
1.2	1.0, but assuming steepness (h) of 1
1.3	1.0, but assuming steepness (h) of 0.5
1.4	1.0, but assuming maximum exploitation rate (U^{max}) of 0.9
1.5	1.0, but assuming maximum exploitation rate (U^{max}) of 0.65
2.0	1.0, fixed growth parameters at low values
3.0	1.0, fixed growth parameters at high values

The base case model appeared to have represented most observational data well, and there is no obvious indication of lack of fit. The CPUE shape parameter was estimated to be less than 1, suggesting possible hyper-stability in the relationship between CPUE and abundance. However, model results changed very little when a linear relationship between CPUE and abundance was assumed.

Model sensitivity runs which assumed different values for the stock-recruitment steepness (h) parameter appeared to compensate for the differences in the stock-recruitment relationship with changes in R_0 , recruitment deviations, and natural mortality. Estimates of current stock status were similar between these model runs, although there were some differences in the size of the estimated B_0 .

Table 6: Summary of the marginal posterior distributions from the MCMC chain from the base case (1.0). The columns show the 5th and 95th percentiles, and the medians. Biomass is in tonnes.

	5%	Median	95%	MPD estimate
B_0	3905	4242	4541	4156
B_{ref}	1299	1426	1561	1359
$B_{current}$	790	933	1115	877
$B_{current} / B_0$	0.19	0.22	0.26	0.21
$B_{current} / B_{ref}$	0.56	0.66	0.78	0.65
B_0^r	3063	3417	3719	3368
B_{ref}^r	669	816	971	777
$B_{current}^r$	261	334	428	313
$B_{current}^r / B_0^r$	0.08	0.10	0.12	0.09
$B_{current}^r / B_{ref}^r$	0.32	0.41	0.54	0.40
$U_{current}$	0.33	0.41	0.49	0.43

The base case assumed a maximum exploitation rate (U_{max}) of 0.8 and there were two years (2001 and 2003) in which the exploitation rate was estimated to be at this bound. When U_{max} was assumed to be 0.65, the estimated exploitation rates for 2001 and 2003 were also at the bound; when U_{max} was assumed to be 0.9, the estimated exploitation rate for 2003 was at the bound. However, biomass estimates were similar among all these runs.

The base case assessment estimated growth parameters within the model using the tag-recapture data. The fits to the tag-recapture data appear adequate, but are likely to have been influenced by the proportion-at-length data as well. Sensitivity runs, which assumed alternative growth parameters (fixed at values representing either a fast or slow growth rate), led to significant changes to the estimates of abundance, but had poor fits to the proportion-at-length data.

Figure 5: Posterior distributions of spawning stock biomass as a percentage of virgin level from MCMC 1.0. The box shows the median of the posterior distribution (horizontal bar), the 25th and 75th percentiles (box), with the whiskers representing the full range of the distribution. The target is the median reference biomass (33.6% B_0).

The base case estimated growth parameters within the model incorporating the tag-recapture data. The fits to the tag-recapture data appear adequate, but are likely to have been influenced by the proportion-at-length data. Sensitivity runs assuming alternative growth parameters (fixed at values representing either a fast or slow growth rate) led to significant changes to the estimates of abundance, but had poor fits to the proportion-at-length data.

4.5 Yield estimates and projections

No estimate of *MCY* has been made for PAU 7.

No estimate of *CAY* has been made for PAU 7.

4.6 Other factors

The stock assessment model assumed homogeneity in recruitment, that natural mortality does not vary by size or year, and that growth has the same mean and variance throughout the entire area. However, it is known that paua fisheries are spatially variable and that apparent growth and maturity in paua populations can vary over very short distances. Variation in growth is addressed to some extent by having a stochastic growth transition matrix based on tagging data collected from a range of different locations. Similarly, the length frequency data are integrated across samples from many places. The effect of this integration across local areas is likely to make model results optimistic. For instance, if some local stocks are fished very hard and others not fished, local recruitment failure can result due to the limited dispersal range of this species. Recruitment failure is a common observation in overseas abalone fisheries. Fishing may also cause spatial contraction of populations (e.g., Shepherd & Partington 1995), and some populations appear to become relatively unproductive after initial fishing (Gorfine & Dixon 2000). If this happens, the assessment will overestimate productivity in the

population as a whole. It is also possible that good recruitments estimated by the model might have been the result of serial depletion.

Table 7: Projections to 2014 of the key indicators (from the base case MCMC) with future commercial catch set to 100%, 90%, 85%, and 80% of the TACC. Key indicators are spawning stock biomass (B) and recruited biomass (rB) and include % of virgin biomass and % biomass from a reference period (B_{ref}) and the probability of being above current biomass or below default limits.

Projection	2011	2014			
		Current TACC	90% TACC	85% TACC	80% TACC

CPUE provides information in the model on changes in relative abundance. However, CPUE is generally considered to be a poor index of stock abundance for paua, due to divers' ability to maintain catch rates by moving from area to area despite a decreasing biomass (hyperstability). Breen et al (2003) argued that standardised CPUE might monitor changes of abundance in a fully exploited fishery, and that declines in the CPUE most likely reflected a decline in the population. PAU 7 is generally considered to be a fully developed fishery: the exploitation rate in Statistical Areas 017 and 038 is known to have been high and there are unlikely to be many unfished areas within the area.

Commercial catch length frequencies provide information on changes in population structure under fishing pressure. However, if serial depletion has occurred and fishers have moved from area to area, samples from the commercial catch may not correctly represent the population of the entire stock. For PAU 7, there has been a long time-series of commercial catch sampling and the spatial coverage of the available samples is generally considered to be adequate throughout the years.

The utility of research diver survey indices to provide relative abundance information has been an ongoing concern in the SFWG. Cordue (2009) identified issues associated with diver surveys based on the timed swim approach and questioned their adequacy as indices of relative abundance. Haist (2010) suggested that the existing RDSI data were likely to be more useful at a stratum level. The general consensus is that the index-abundance relationship from the research diver survey is likely to be nonlinear, and cannot easily be quantified in a stock assessment.

5. STATUS OF THE STOCKS

Stock Structure Assumptions

The 2012 assessment was conducted for Statistical Areas 017 and 038 only, but these include most (more than 90%) of the recent catch.

- PAU 7- *Haliotis iris*

Stock Status	
Year of Most Recent Assessment	2012
Assessment Runs Presented	Base case MCMC
Reference Points	Interim Target: B_{ref} (average spawning biomass from 1985–1987) = 33.6% B_0 Soft Limit: 20% B_0 Hard Limit: 10% B_0
Status in relation to Target	Spawning stock biomass was estimated to be 66% B_{ref} and is Very Unlikely (< 10%) to be at or above the interim target
Status in relation to Limits	Spawning stock biomass was estimated to be 22% B_0 , and is About as Likely as Not (40–60%) to be below the soft limit and Unlikely (< 40%) to be below the hard limit

Historical Stock Status Trajectory and Current Status

Posterior distributions of spawning stock biomass as a percentage of virgin level from MCMC 1.0. The box shows the median of the posterior distribution (horizontal bar), the 25th and 75th percentiles (box), with the whiskers representing the full range of the distribution. The target is the median reference biomass (33.6% B_0).

Projections and Prognosis	
Stock Projections or Prognosis	Three year projections indicate that spawning and recruited biomass are likely to increase but are Very Unlikely (< 10%) to be at or above the target by this time.
Probability of Current Catch or TACC causing decline below Limits	Soft Limit: About as Likely as Not (40–60%) Hard Limit: Unlikely (< 40%)

Assessment Methodology & Evaluation

Assessment Type	Full quantitative stock assessment	
Assessment Method	Length based Bayesian model	
Assessment Dates	Latest: 2012	Next: 2015
Overall assessment quality rank	1 – High Quality	
Main data inputs (rank)	- CPUE	1 – High Quality 2 – Medium or Mixed Quality: it is

	<ul style="list-style-type: none"> - Research diver survey indices - Commercial catch length frequency - Research diver length frequency - Tag-recapture data - Maturity at length data 	<p>suggested that the RDSI do not provide a reliable index of abundance</p> <p>1 – High Quality</p> <p>1 – High Quality</p> <p>1 – High Quality</p> <p>1 – High Quality</p>
Data not used (rank)	-	
Changes to Model Structure and Assumptions	- Data weighting (LF only) and steepness	
Major Sources of Uncertainty	<ul style="list-style-type: none"> - Spatial heterogeneity not incorporated - Potential hyperstability in CPUE - Potential for localised recruitment failure 	

Qualifying Comments

No account has been taken of the voluntary closure of areas affected by “greening”. Stock projections also do not account for reduced production due to potential closed areas in the future, which are likely to slow or reverse projected increases in stock size.

PILCHARD (PIL)

(*Sardinops sagax*)

Mohimohi

1. FISHERY SUMMARY

Pilchards were introduced into the QMS in October 2002 with allowances, TACCs and TACs as shown in Table 1.

Table 1: Recreational and Customary non-commercial allowances, TACCs and TACs by Fishstock.

Fishstock	Recreational Allowance	Customary Non-commercial Allowance	TACC	TAC
PIL 1	20	10	2 000	2 030
PIL 2	10	5	200	215
PIL 3	5	2	60	67
PIL 4	3	2	10	15
PIL 7	10	5	150	165
PIL 8	10	5	65	80
PIL 10	0	0	0	0

1.1 Commercial fisheries

Pilchards occur around most of New Zealand, however, commercial fisheries have only developed in north-eastern waters (east Northland to Bay of Plenty), and in Tasman Bay and Marlborough Sounds at the north of the South Island.

The first recorded commercial landings of pilchards were in 1931 (Table 2), but a minor fishery existed before this. Informal sales, mainly as bait, or as food for zoos and public aquariums, were unreported. A fishery for pilchard developed in the Marlborough Sounds in 1939 and operated through the war years providing canned fish for the armed forces. Landings reached over 400 t in 1942, but the fishery was unsuccessful for a variety of reasons and ceased in 1950. Between 1950 and 1990 landings were generally less than 20 t, intermittently reaching 70–80 t.

From 1990–91 the northeastern fishery was developed by vessels using both lampara nets and purse seines (Table 3). Lampara netting was the main method in the first couple of years, and continued at a low level through the 1990s. From 1993–94 onwards, purse seining became the dominant method. A diminishing catch (less than 10 t annually) was caught by beach seine. Almost all the pilchard catch (particularly in the northeastern fishery) is targeted. A small catch (less than 10 t annually), has been

recorded as a bycatch of jack mackerel targeting. Total annual landings increased steadily from 1990 as the fishery developed in northeastern waters, reaching over 1200 t in 1999–00, and almost 1500 t in 2000–01. Landings declined consistently after 2003–04, largely influenced by catches from PIL 1, and since 2010–11 have been between 221 and 391t. Landings in PIL 8 have fluctuated between 12 t and 153 t since this stock was introduced to the QMS, and have not exceeded the TACC (65 t) in the last five years. The sudden increase in catches in PIL 8 from 1999–2000 to 2005–6 was thought to be in part the result of previously unreported catches now being reported due to the species being introduced to the QMS. Figure 1 depicts the historical landings and TACC values for the main PIL stocks.

Table 2: Reported total New Zealand landings (t) of pilchard from 1931 to 1990.

Year	Landings	Year	Landings	Year	Landings	Year	Landings	Year	Landings	Year	Landings
1931	5	1941	168	1951	0	1961	17	1971	1	1981	17

Source: Annual reports on fisheries and subsequent MAF data.

A 2000 t annual Commercial Catch Limit (CCL) was introduced for FMA 1 from 01 October 2000. The CCL was subject to a logbook programme, a catch spreading arrangement and the avoidance of areas of particular importance to non-commercial fishers. The CCL was superseded when the PIL 1 stock was introduced to the QMS with a TACC of 2000 t on 1st October 2002.

1.2 Recreational fisheries

Recreational fishers seldom target pilchards, except perhaps for bait. However bait is generally bought in commercially frozen packs (the main product of the commercial fishery). Pilchard may be caught

PILCHARD (PIL)

accidentally in small mesh nets that are set or dragged to catch mullet, or on small hooks fished from wharves. They are rarely reported as a catch in recreational fishing activities. An estimate of the recreational harvest is not available.

Figure 1: Historical landings and TACC for the two main PIL stocks. Left to right: PIL 1 (Auckland East), and PIL 8 (Central Egmont, Auckland West).

1.3 Customary non-commercial catch

Pilchards were known by the early Maori as mohimohi, and could have been taken in fine mesh nets, but there are very few accounts of pilchard capture and use. An estimate of the current customary non-commercial catch is not available.

1.4 Illegal catch

There is no known illegal catch of pilchards.

1.5 Other sources of mortality

Some accidental captures by vessels purse seining for jack mackerel or kahawai may be discarded if no market is available. Pilchard mortality is known to be high in some places as a result of scale loss resulting from net contact.

2. BIOLOGY

The taxonomy of *Sardinops* is complex. The New Zealand pilchard was previously identified as *Sardinops neopilchardus*, but there is now considered to be a single species, *S. sagax*, with several regional subspecies or populations.

Pilchard are generally found inshore, particularly in gulfs, bays, and harbours. They display seasonal changes in abundance (e.g. locally abundant in Wellington Harbour during spring), reflecting schooling and dispersal behaviour, localised movement, and actual changes in population size. The geographical extent of their movements in New Zealand is unknown.

Their vertical distribution in the water column varies, but on the inner shelf they move between the surface and the seafloor. Pilchards form compact schools (known as 'meatballs'), particularly during summer, and these are heavily preyed upon by larger fishes, seabirds, and marine mammals and are thought to form an important part of the diet for many species. There have been no biological studies that are directly relevant to the recognition of separate stocks.

Spawning is recorded from many coastal regions over the shelf during spring and summer. The pelagic eggs are at times extremely abundant.

Otolith readings suggest that pilchard are relatively fast growing and short-lived. They reach a maximum length of about 25 cm, and perhaps 9 years, but the main size range is of 10–20 cm fish, 2 to 6 years old. Maturity is probably at age 2.

A study on the feeding of Northland pilchards found that phytoplankton was probably the dominant food, but organic detritus was also important, and small zooplankton - mainly copepods - were taken and at times were the main component. Feeding by females diminished during the spawning season.

Although they generally comprise single-species schools, pilchards associate with other small pelagic fishes, particularly anchovy. In northern waters they also occur with juvenile jack mackerel, and in southern waters with sprats.

During the 1990s pilchard populations were severely impacted by natural mass mortalities, generally attributed to a herpes virus. The first outbreak occurred in Australia and New Zealand in 1995 and Australia experienced another outbreak in 1998.

Biological parameters relevant to stock assessment are shown in Table 4.

Table 4: Estimates of biological parameters.

Fishstock		Estimate	Source
<u>1. Natural mortality (M)</u>			
PIL 1		$M = 0.66$	NIWA, unpublished estimate ¹
PIL 1		$M = 0.46$	NIWA, unpublished estimate ²
<u>2. Weight = a (length)^b</u>			
		<u>Both sexes combined</u>	
PIL 1	a = 2.2	b = 3.3	Paul et al (2001) ³
PIL 7	a = 3.7	b = 3.3	Baker (1972) ⁴

Notes:

1. Hoenig's rule-of-thumb estimate, maximum age = 7 years.
2. Hoenig's rule-of-thumb estimate, maximum age = 10 years.
3. Fork length in mm, weight in g, n = 493.
4. Standard length in mm, weight in g, n = 660.

3. STOCKS AND AREAS

No biological information is available on which to make an assessment on whether separate pilchard biological stocks exist in New Zealand (in Australia there is evidence of small differences between some populations off the southwest coast).

Pilchard and anchovy are often caught together. Pilchard Fishstock boundaries are fully aligned with those for anchovy.

4. STOCK ASSESSMENT

There have been no stock assessments of New Zealand pilchard.

4.1 Estimates of fishery parameters and abundance

No fishery parameters are available.

4.2 Biomass estimates

No estimates of biomass are available.

4.3 Yield estimates and projections

(i) Northeast North Island (PIL 1)

MCY has been estimated using the equation $MCY = cY_{AV}$ (Method 4). The most appropriate Y_{AV} was considered the average of landings for the three years 1998–99 to 2000–01. Although a brief period, three years represents at least half the exploited life span for this species. The mean of these landings is 1101 t. With provisional values of M about 0.4 or 0.6, the value of c becomes 0.6 (i.e. high natural variability).

1998–99 to 2000–01 $MCY = 0.6 * 1101 \text{ t} = 661 \text{ t}$ (rounded to 660 t)

However, the *MCY* approach is considered to be of limited value for pilchards, because this fishery has been developing rapidly, was historically infrequently targeted, and since 2000 has been subject to a CCL and more recently a TACC. The level of risk to the stock by harvesting the northeast North Island population at the estimated *MCY* value cannot be determined.

(ii) Tasman Bay/Marlborough Sounds (PIL 7)

MCY cannot be estimated for this region because the fishery has been largely unexploited since the 1940s, and no appropriate biological parameters exist.

(iii) Other regions

MCY cannot be estimated because of insufficient information, and absence of fisheries.

Current biomass cannot be estimated, so *CAY* cannot be determined.

4.4 Other factors

It is likely that pilchard, although not strongly migratory, will vary considerably in their regional abundance over time. The larger vessels in the fleet that targets them are capable of travelling moderate distances to the best grounds. Thus, while the resource may have a relatively localised distribution, the catching sector of the fishery does not. Should the pilchard fishery develop again after recent decline it is likely to become one component of a set of fisheries for small pelagic species (anchovy, sprats, and small jack mackerels). Mixed catches will be inevitable.

Pilchard is abundant in some New Zealand regions. However, it is unlikely that the biomass is comparable to the very large stocks of pilchard (sardine) in some world oceans where strong upwelling promotes high productivity. It is more likely that the New Zealand pilchard comprises abundant but localised coastal populations, comparable to those of southern Australia. They appear to be adaptable feeders, able to utilise food items from organic detritus through phytoplankton to zooplankton. East Northland is a region where under neutral to El Niño conditions moderately productive upwelling predominates, but in La Niña years downwelling and oceanic water incursion will limit recruitment and may affect adult condition and survival.

In those regions of the world where small pelagic fishes are particularly abundant and have been well studied, there is often a reciprocal relationship between the stock size of pilchard and anchovy, as well as great variability in their overall abundance. Many pilchard/anchovy fisheries have undergone boom-and-bust cycles.

In both Australia and New Zealand, pilchard have been affected by mass mortality events, the two in Australia are estimated to have each killed over 70% of the adult fish. The mortality rate of the 1995 event in New Zealand is not known, but was high. In combination, these features of the pilchard's biology suggest that the yield from the New Zealand stock will be variable, both short-term (annual) and long-term (decadal).

5. STATUS OF THE STOCKS

MCY estimates for PIL are considered unreliable. It is not known if the current catches or TACCs are sustainable.

Yield estimates, TACCs and reported landings by Fishstock are summarised in Table 5.

Table 5: Summary of yield estimates (t), TACCs (t), and reported landings (t) of pilchards for the most recent fishing year.

Fishstock	FMA	<i>MCY</i> Estimates	2012–13	2012–13	
			Actual TACC	Reported landings	
PIL 1	Auckland (East)	1	660	2 000	332

Pipi (PPI)

(*Paphies australis*)

Pipi

1. FISHERY SUMMARY

Pipi are important shellfish both commercially and for non-commercial fishers. PPI 1A (which is located in Whangarei harbour and mapped in the following PPI 1A section) was introduced into the Quota Management System (QMS) on 1 October 2004, the other PPI stocks listed in Table 1 were introduced in October 2005. The total TAC introduced to the QMS was 713 t. This consisted of a 204 t TACC, an allocation of 242 t for both recreational allowance and customary allowance and 25 t allowance for other sources of mortality (Table 1). No changes have occurred to the TAC since. The fishing year is from 1 October to 30 September and commercial catches are measured in greenweight. The largest commercial fishery is in PPI 1A and the largest recreational fishery is in PPI 1C.

Table 1: Recreational, Customary non-commercial allocations, TACs and TACCs (t) for pipi.

Fishstock	Recreational Allowance	Customary non-commercial allowance	Other sources of mortality	TACC	TAC
PPI 1A	25	25	0	200	250
PPI 1B	76	76	8	0	160
PPI 1C	115	115	10	3	243
PPI 2	3	3	1	0	7
PPI 3	9	9	1	0	19
PPI 4	1	1	1	0	3
PPI 5	1	1	1	0	3
PPI 7	1	1	1	1	4
PPI 8	1	1	1	0	3
PPI 9	10	10	1	0	21
Total	242	242	25	204	713

Regulations require that all commercial gathering is to be done by hand. Fishers typically use a mask and snorkel. There is no minimum legal size (MLS) for pipi, although fishers probably favor larger pipi (over 60 mm shell length). There is no apparent seasonality in the pipi fishery, as pipi are

PIPI (PPI)

available for harvest year-round. Some commercial catch is taken from PPI 1C (Table 2 and Figure 1) but the great majority of commercial catch is reported from PPI 1A and this will be dealt with in a separate section.

New Zealand operates a mandatory shellfish quality assurance programme for all areas of commercially growing or harvesting bivalve shellfish for human consumption. Shellfish caught outside this programme can be sold only for bait. This programme is based on international best practice and is managed by MPI in cooperation with the District Health Board Public Health Units and the shellfish industry¹. Before any area can be used to grow or harvest bivalve shellfish, public health officials survey both the water catchment area to identify any potential pollution issues and microbiologically sample water and shellfish over at least a 12-month period, so that all seasonal influences are explored. This information is evaluated and, if suitable, the area classified and listed by NZFSA for harvest. There is then a requirement for regular monitoring of the water and shellfish flesh to verify levels of microbiological and chemical contaminants. Management measures stemming from this testing include closure after rainfall, to deal with microbiological contamination from runoff. Natural marine biotoxins can also cause health risks so testing also occurs for this at regular intervals. If toxins are detected above the permissible level the harvest areas are closed until the levels fall below the permissible level. Products are also traceable so the source and time of harvest can always be identified in case of contamination.

Table 2: Reported commercial landings of pipi (t greenweight) from PPI 1C from 2004–05 to present.

Year	Reported landings (t)	Limit (t)
2004–05	0	3
2005–06	0.86	3
2006–07	1.69	3
2007–08	1.80	3
2008–09	0.38	3
2009–10	0.62	3
2010–11	0	3
2011–12	0	3
2012–13	0	3

¹. For full details of this programme, refer to the Animal Products (Regulated Control Scheme-Bivalve molluscan Shellfish) Regulations 2006 and the Animal Products (Specifications for Bivalve Molluscan Shellfish) Notice 2006 (both referred to as the BMSRCS), at: <http://www.foodsafety.govt.nz/industry/sectors/seafood/bms/growers-harvesters.htm>

1.2 Recreational fisheries

The recreational fishery is harvested entirely by hand digging. Large pipi 50 mm (maximum shell length) or greater are probably preferred. The 1996, 1999–00, and 2000–01 National Marine Recreational Fishing Surveys recorded recreational harvests for pipi in FMA 1. The estimated numbers of pipi harvested were 2.1, 6.6, and 7.2 million respectively but no mean harvest weight was available to convert these harvest estimates to tonnages. The Recreational Technical Working Group concluded that the harvest estimates from the diary surveys should be used only with the following qualifications: a) they may be very inaccurate; b) the 1996 and earlier surveys contain a methodological error; and, c) the 2000 and 2001 estimates are implausibly high for many important fisheries. No recreational harvest estimates specific to the Mair Bank pipi fishery are available but the recreational harvest of pipi is likely to be small compared with commercial landings there.

1.3 Customary fisheries

In common with many other intertidal shellfish, pipi are very important to Maori as a traditional food. However, no reliable quantitative information on the level of customary take is available.

1.4 Illegal catch

No quantitative information on the level of illegal catch is available.

1.5 Other sources of mortality

No quantitative nationwide information on the level of other sources of mortality is available.

2. BIOLOGY

The pipi (*Paphies australis*) is a common burrowing bivalve mollusc of the family Mesodesmatidae. Pipi are distributed around the New Zealand coastline, including the Chatham and Auckland Islands (Powell 1979), and are characteristic of sheltered beaches, bays and estuaries (Morton & Miller 1968). Pipi are tolerant of moderate wave action, and commonly inhabit coarse shell sand substrata in bays and at the mouths of estuaries where silt has been removed by waves and currents (Morton & Miller 1968). They have a broad tidal range, occurring intertidally and subtidally in high-current harbour channels to water depths of at least 7 m (Dickie 1986a, Hooker 1995a), and are locally abundant, with densities greater than 1000 m⁻² in certain areas (Grace 1972).

Pipi reproduce by free-spawning, and most individuals are sexually mature at about 40 mm shell length (SL) (Hooker & Creese 1995a). Gametogenesis begins in autumn, and by late winter many pipi have mature, ready-to-spawn gonads (Hooker & Creese 1995a). Pipi have an extended breeding period from late winter to late summer, with greatest spawning activity occurring in spring and early summer. Fertilised eggs develop into planktotrophic larvae, and settlement and metamorphosis occur about three weeks after spawning (Hooker 1997). In general, pipi have been considered sedentary when settled, although Hooker (1995b) found that pipi may utilise water currents to disperse actively within a harbour. The trigger for movement is unknown, but this ability to migrate may have important implications to their population dynamics.

Pipi growth dynamics are not well known. Growth appears to be fairly rapid, at least in dynamic, high-current environments such as harbour channels. Hooker (1995a) showed that pipi at Whangateau Harbour (northeastern New Zealand) grew to about 30 mm in just over one year (16–17 months), reached 50 mm after about three years, and grew very slowly after attaining 50 mm. There was a strong seasonal component to growth, with rapid growth occurring in spring and summer, and little growth in autumn and winter. Williams et al (2007) used Hooker's (1995a) tag-recapture and length frequency time series data to generate formal growth estimates for Whangateau Harbour pipi (Table 3). Estimates are also available from time series of size frequencies on sheltered Auckland beaches (Table 3; Morrison & Browne 1999, Morrison et al 1999), although these were likely to have been poorly estimated due to variability in the length data. Growth on the intertidal section of Mair bank was estimated by (Pawley et al 2013) using the results of a notch-tagging experiment in 2009–10.

PIPI (PPI)

These estimates are likely to underestimate growth of pipi in the commercial fishery because tagged shells came from the intertidal zone whereas commercial harvesting is conducted primarily in the subtidal (where growth is expected to be quicker).

Little is known about the natural mortality or maximum longevity of pipi. Haddon (1989) suggested that pipi are unlikely to live much more than 10 years, and used assumed maximum ages of 10, 15 and 20 years old to estimate maximum constant yield for Mair Bank pipi in 1989. The estimation of the rate of instantaneous natural mortality (M) is difficult for pipi owing to the immigration and emigration of individuals from different areas. As the timing and frequency of these movements are largely unknown, the separation of mortality from movement effects is likely to be problematic. Williams et al (2007) assumed values of $M = 0.3, 0.4,$ and 0.5 to estimate yields for Mair Bank in 2005–06.

Table 3: Estimates of biological parameters for pipi.

Growth		Location	Year	Source
L_{∞} (mm SL)	K			
57.3	0.46	inner Whangateau Harbour site	1992–93	Williams et al (2007)
63.9	0.57	Whangateau Harbour entrance	1992–93	Williams et al (2007)
41.1	0.48	Cheltenham Beach, North Shore	1997–98	Morrison et al (1999)
58.9	0.15	Mill Bay, Manukau Harbour	1997–98	Morrison et al (1999)
84.6	0.09	Mill Bay, Manukau Harbour	1998–99	Morrison & Browne (1999)
Natural mortality				
$M = 0.3$ – 0.5 (assumed values)		-	-	Williams et al (2007)
Size at maturity				
40 mm SL		Whangateau Harbour	-	Hooker & Creese (1995a)

3. STOCKS AND AREAS

Little is known of the stock structure of pipi. A study of biological connectivity that is currently underway includes pipi, but no results have been reported at the time of this report.

4. STOCK ASSESSMENT

There is a stock assessment for PPI 1A.

5. STATUS OF THE STOCKS

There were negligible reported landings in 2012–13 for any PPI stocks except PPI 1A (which is reported separately). The status of all PPI stocks other than PPI 1A are unknown, but are assumed to be close to virgin biomass.

PIPI (PPI)

PPI (PPI 1A) Mair Bank (Whangarei Harbour)

(Paphies australis)

Pipi

1. FISHERY SUMMARY

Pipi 1A was introduced into the Quota Management System (QMS) on 1 October 2004 with a TAC of 250 t, comprising a TACC of 200 t, and customary and recreational allowances of 25 t each. These limits have remained unchanged since.

1.1 Commercial fisheries

Prior to the introduction of pipi, in Whangarei Harbour (PPI 1A) and FMA PPI 1, to the QMS in 2004, the commercial fishery area was defined in regulation as that area within 1.5 nautical miles of the coastline from Home Point, at the northern extent of the Whangarei Harbour entrance, to Mangawhai Heads, south of the harbour. Commercial fishers tend to gather pipi from the seaward edge of Mair Bank, particularly the southern end, and avoid the centre of the bank itself where there is a lot of shell debris. Regulations require that all gathering be done by hand, and fishers typically use a mask and snorkel. There is no minimum legal size (MLS) for pipi, although a sample measured from the commercial catch in PPI 1A in 2005 suggested that fishers favour larger pipi (over 60 mm SL, Williams et al 2007). Pipi are available for harvest year-round, so there is no apparent seasonality in the fishery.

Over 99% of the total commercial landings of pipi in New Zealand have been from general statistical area 003 and PPI 1. In the most recent years, where a distinction has been made, virtually all the landings have been from PPI 1A (Whangarei Harbour). Total commercial landings of pipi reported on Licensed Fish Receiver Returns (LFRRs) have remained reasonably stable through time, averaging 187 t annually in New Zealand since 1986–87 (Table 1). The highest recorded landings were in 1991–92 (326 t). There is no evidence of any consistent seasonal pattern in either the level of effort or catch per unit effort (CPUE) in the pipi fishery. CPUE in the pipi targeted fishery increased between 1989–90 and 1992–93, was then relatively stable up to 2002–03 but increased in 2003–04 and 2004–05 (Williams et al 2007). No CPUE information has since been analysed.

Prior to the introduction of PPI 1A to the QMS there were nine permit holders for Whangarei Harbour. No new entrants have entered the fishery since 1992 when commercial access to the fishery was constrained by the general moratorium on granting new fishing permits for non-QMS fisheries. Access to the fishery has, however, been restricted through other regulations since the mid-1980s, and more formally since 1988. Under previous non-QMS management arrangements, there was a daily

catch limit of 200 kg per permit holder, meaning that, collectively, the nine permit holders could, theoretically, take 657 t of pipi per year. The permit holders have indicated that annual harvest quantities have been considerably less than the potential maximum, because of the relatively low market demand for commercial product rather than the availability of the resource. On 1 October 2004, pipi in Whangarei Harbour (PPI 1A) were introduced into the QMS, and the nine existing permits were replaced with individual transferable quotas. The 200 kg daily catch limit no longer applies. A total allowable catch (TAC) of 250 t was set, comprised of a total allowable commercial catch (TACC) of 200 t, a customary allowance of 25 t, and a recreational allowance of 25 t. Figure 1 shows the historical landings and TACC values for PPI 1A.

Table 1: Reported commercial landings (from Licensed Fish Receiver Returns; LFRR) of pipi (t greenweight) in New Zealand since 1986–87. Prior to the introduction of PPI 1A to the QMS on 1 October 2004, the fishery was limited by daily limits which summed to 657 t greenweight in a 365 day year, but there was no explicit annual restriction. A TACC of 200 t was set for PPI 1A on 1 October 2004.

Year	Reported landings (t)	Limit (t)	Year	Reported landings (t)	Limit (t)
1986–87	131	657	1999–00	143	657
1987–88	133	657	2000–01	184	657
1988–89	134	657	2001–02	191	657
1989–90	222	657	2002–03	191	657
1990–91	285	657	2003–04	266	657
1991–92	326	657	2004–05	206	200
1992–93	184	657	2005–06	137	200

			2012–13	0	200

Figure 1: Historical landings and TACC for PPI 1A (Whangarei Harbour). QMS data from 2004–05 to present.

1.2 Recreational fisheries

This is covered in the general pipi section.

1.3 Customary non-commercial fisheries

This is covered in the general pipi section.

PIPI (PPI)

1.4 Illegal catch

This is covered in the general pipi section.

1.5 Other sources of mortality

There is some concern about the possibility of changes in bank stability that could arise from operations other than fishing in Whangarei Harbour (e.g., harbour dredging, port developments), which could lead to changes in the pipi fishery. Radical changes to the local hydrology could affect the size or substratum of Mair Bank with consequent effects on its pipi population. Also, as suspension feeders, pipi may be adversely affected by increased sediment loads in the water column.

2. BIOLOGY

This is covered in the general pipi section.

3. STOCKS AND AREAS

Little is known of the stock structure of pipi. A study of biological connectivity that is currently underway includes pipi, but no results have not been finalised at the time of this report. The commercial fishery based on Mair Bank in Whangarei Harbour (PPI 1A) forms a geographically discrete area and is assumed for management purposes to be a separate stock.

4. STOCK ASSESSMENT

Stock assessment for Mair Bank pipi was conducted in 2005 and 2010 using absolute biomass surveys, and yield per recruit and spawning stock biomass per recruit modelling.

4.1 Estimates of fishery parameters and abundance

Estimates of the fishing mortality reference point $F_{0.1}$ are available from yield per recruit modeling (Table 2). Parallel spawning stock biomass per recruit modeling was conducted to estimate the SSBPR corresponding with each estimate of $F_{0.1}$. These estimates are sensitive to the assumed value of natural mortality (M) and uncertainty in pipi growth parameters.

Table 2: Estimates of the reference rate of fishing mortality $F_{0.1}$ and corresponding spawning stock biomass per recruit at three different assumed rates of natural mortality (M) for two harvest strategies ('no restriction' and 'current'). SL, shell length (at recruitment). Estimates from Williams et al (2007).

'No restriction' strategy (harvest pipi of a size that maximizes YPR)					
Assumed M	Optimal age at recruitment (y)	SL (mm)	$F_{0.1}$	YPR (g)	SSBPR (%)
0.3	3	52	0.437	4.93	44
0.4	2.75	51	0.550	3.50	45
0.5	2.5	49	0.648	2.58	45
'Current' strategy (harvest pipi 60 mm and over)					
Assumed M	Age at recruitment (y)	SL (mm)	$F_{0.1}$	YPR (g)	SSBPR (%)
0.3	5	60	0.564	3.98	62
0.4	5	60	0.755	2.41	70
0.5	5	60	0.949	1.47	76

4.2 Biomass estimates

Virgin biomass (B_0) and the biomass that will support the maximum sustainable yield (B_{MSY}) are unknown for Mair Bank pipi. Only three biomass estimates have been made for the Mair Bank pipi population: in 1989 using a grid survey, in 2005 using stratified random sampling and in 2010 using a systematic random start. The 1989 estimate of 2245 t ($\pm 10\%$) can be considered conservative because only the intertidal area of the bank was surveyed, and pipi are known to exist in the shallow subtidal area of the bank. Estimates of biomass are available for Mair Bank and are sensitive to the assumed size at recruitment (Table 3).

Table 3: Estimated recruited biomass (*B*) of pipi on Mair Bank in 2005 and 2010 for different assumed sizes at recruitment to the fishery. Source: Williams et al (2007) and Pawley et al (2013).

Year	Assumed shell length at recruitment (mm)	Intertidal stratum		Subtidal stratum		Mair Bank Total	
		<i>B</i> (t)	CV (%)	<i>B</i> (t)	CV (%)	<i>B</i> (t)	CV (%)
2005	1 (total biomass)	3 602	11.4	6 940	19.5	10 542	13.4
2005	40	3 569	11.4	6 922	19.5	10 490	13.4
2005	45	3 434	11.4	6 791	19.6	10 226	13.6
2005	50	2 986	11.3	5 989	20.1	8 975	14.0
2005	55	2 022	11.1	3 855	23.8	5 877	16.0
2005	60	1 004	13.1	2 013	37.5	3 017	25.4
2010	1 (total biomass)	2 233	17.4	2 218	33.0	4 452	15.2
2010	50	2 001	18.1	1 889	36.0	3 890	16.6
2010	60	1 751	18.3	1 393	33.7	3 145	17.4

4.3 Yield estimates and projections

Maximum Constant Yield (*MCY*) was estimated using method 2 (see the guide to biological reference points in the introduction chapter of this plenary document):

$$MCY = 0.5F_{0.1}B_{av}$$

where $F_{0.1}$ is a reference rate of fishing mortality and B_{av} is the historical average recruited biomass (estimated as the mean recruited biomass from the 2005 and 2010 surveys). M is assumed to be 0.3 and the corresponding $F_{0.1}$ is 0.564 (Williams et al 2007 revised version). The size at recruitment is assumed to remain at 60 mm and the corresponding B_{av} is 3081 t.

$$MCY = 0.5 \times 0.564 \times 3081 = 869 \text{ t}$$

This estimate of *MCY* would have a CV at least as large as those associated with the 2005 and 2010 estimates of recruited biomass (17–25%), and is sensitive to the assumed size at recruitment to the fishery, the assumed natural mortality, and to uncertainty in $F_{0.1}$ (arising from the considerable uncertainty in model input values for growth and M) (Table 4).

Table 4: Sensitivity of maximum constant yield (*MCY*, method 2) to estimates of size at recruitment and the assumed natural mortality, M . B_{av} , the historical average recruited biomass, was estimated for two sizes at recruitment (50 and 60 mm SL) using the 2005 and 2010 survey data.

SL at recruitment (mm)	B_{av}	M	$F_{0.1}$	<i>MCY</i> (t)
50	6433	0.3	0.40	1 300
		0.4	0.54	1 729
		0.5	0.68	2 182
60	3081	0.3	0.56	869
		0.4	0.76	1 163
		0.5	0.95	1 462

CAY was not estimated because there is no estimate of current biomass.

4.4 Other factors

None

5. STATUS OF THE STOCKS

Stock Structure Assumptions

For the purpose of this assessment PPI 1A is assumed to be a discrete stock.

Stock Status	
Year of Most Recent Assessment	2012
Reference Points	Target(s): Default 40% B_0 Soft Limit: 20% B_0 Hard Limit: 10% B_0
Status in relation to Target	Likely (> 60%) to be above target
Status in relation to Limits	Soft Limit: Very Unlikely (< 10%) to be below limit. Hard Limit: Very Unlikely (< 10%) to be below limit.
Historical Stock Status Trajectory and Current Status	
Biomass (t) of pipi ≥ 50 mm shell length from Moir Bank.	

Fishery and Stock Trends	
Recent Trend in Biomass or Proxy	Complete surveys were conducted in 2005 and 2010. These surveys showed similar recruited biomass (>60 mm SL) but the total and spawning stock biomass (>40 mm SL) were both substantially higher in 2005 than in 2010
Recent Trend in Fishing Mortality or Proxy	Landings continue to be substantially less than estimates of MCY

Projections and Prognosis	
Stock Projections or Prognosis	Stock size is Likely (> 60%) to remain above the target biomass under current catches and TACCs.
Probability of Current Catch or TACC causing decline below Limits	Soft Limit: Unlikely (< 40%) Hard Limit: Unlikely (< 40%)

Assessment Methodology and Evaluation		
Assessment Type	Level 2: Partial Quantitative Stock Assessment	
Assessment Method	Reference rate of fishing mortality applied to absolute biomass estimates from quadrat surveys	
Assessment Dates	Latest assessment: 2012	Next assessment: Unknown
Overall assessment quality rank	1 – High Quality	
Main data inputs (rank)	- Two absolute abundance estimates (quadrat surveys). - Biological parameters for YPR/SSBPR models.	1 – High Quality 1 – High Quality
Data not used (rank)	-	

Changes to Model Structure and Assumptions	None since the 2005 assessment.
Major Sources of Uncertainty	Growth for the subtidal portion of this population is poorly known. The available data come from other areas or the intertidal portion, both of which can be expected to support slower growth than the area where the fishery occurs. This, together with poor information on M and the size at recruitment to the fishery, makes the YPR modeling and reference rate of fishing mortality very uncertain.
Qualifying Comments	
Recruitment appears from the 2005 and 2010 survey length frequency distributions to be variable. This may lead to larger variations in the spawning and recruited biomass than the estimates of biomass suggest.	
Fishery Interactions	
This is a hand-gathering fishery with no substantial bycatch or other interactions.

PORAE (POR)

(Nemadactylus douglasii)
Porae

1. FISHERY SUMMARY

Porae was introduced into the Quota Management System on 1 October 2004 with the following TACs, TACCs and allowances (Table 1). These have not been changed.

Table 1: TACs (t), TACCs (t) and allowances (t) for porae.

Fishstock	Recreational Allowance	Customary non-commercial Allowance	Other sources of mortality	TACC	TAC
POR 1	6	3	4	62	75
POR 2	1	1	1	6	9
POR 3	1	1	1	2	5
POR 10	1	1	1	1	4
Total	9	6	7	71	93

1.1 Commercial fisheries

Commercial catches of porae throughout New Zealand are generally small (Table 2 and Table 3). Annual catches in FMA 1, where the majority of porae are caught, have approximately halved since the early 1990s. Catches in FMAs 2, 3, 7, and 9 have remained low. No catches have been reported from FMAs 4, 5, or 6.

Porae is principally caught as a bycatch in inshore setnet fisheries in northern New Zealand. It is generally taken in association with snapper and trevally in east Northland and Coromandel, and tarakihi and blue moki around Gisborne. Small quantities are taken by bottom longline and trawl fisheries targeting snapper off east Northland and Ninety Mile Beach.

Landings are typically under 10 t and the proportion of vessels reporting catches declined steadily during the 1990s. Fishers may confuse the codes PAR (parore) and POR (porae) when reporting catches, but given that both species occur in shallow northern waters, misreporting is difficult to discern.

PORAE (POR)

Table 2: Reported landings (t) of porae by FMA, fishing years 1989–90 to 2003–04.

	FMA 1	FMA 2	FMA 3	FMA 7	FMA 8	FMA 9	FMA 10
1989–90	98	4	< 1	< 1	< 1	0	0
1990–91	115	2	0	0	< 1	4	0
1991–92	121	5	< 1	0	0	3	0
1992–93	121	8	0	1	< 1	< 1	0
1993–94	77	12	2	0	< 1	1	< 1
1994–95	109	5	0	0	< 1	1	< 1
1995–96	94	8	< 1	< 1	< 1	4	0
1996–97	80	7	< 1	1	< 1	2	0

2011–12	43	62	7	6	< 1	2	0	1	51	71
2012–13	58	62	9	18	0	2	0	1	67	83

1.2 Recreational fisheries

Recreational fishers are likely to catch porae whilst targeting species such as snapper, tarakihi and trevally with either hook and line or setnet. Opportunistic targeting of porae is also likely when spearfishing.

1.3 Customary non-commercial fisheries

There is no quantitative information on customary non-commercial harvest levels of porae. Customary non-commercial fishers are likely to catch small quantities of porae when targeting other species such as snapper, tarakihi and trevally.

2. BIOLOGY

Porae (*Nemadactylus douglasii*) is a common inshore species of northern New Zealand (Kermadec Islands, west Auckland and Northland, east Northland, Hauraki Gulf, and the Bay of Plenty). It is also found at some localities as far south as Kapiti Island, Cook Strait and Kaikoura over the summer months, but has not been recorded around the Chatham Islands. Porae also occurs in southeast Australia (New South Wales to Tasmania), where it is known as the grey or rubberlip morwong.

Porae are generally found on reef/sand interfaces in 10–60 m depth, but have been recorded at 100 m. This diurnal species tends to aggregate to form small to large groups over sandy areas. Adults are thought to occupy distinctive home ranges, with individuals residing in the same area for many years. A study along the east coast of Northland recorded an average of 200 porae for each kilometre of rocky coastline.

Very little is known about the biology of this species. They spawn in late summer and autumn, and have an extended planktonic postlarval stage. Juveniles settle to the seafloor at 8–10 cm long. Although they attain a maximum length of at least 70 cm, the average size is 40–60 cm. They live to at least 30 years and growth is believed to slow substantially at maturity (Ayling & Cox 1984, Francis 2001).

3. STOCKS AND AREAS

There is no biological information to suggest separate stocks around New Zealand. However, evidence of residential behaviour and the fact that they are long-lived, suggests that localised depletion is likely to occur.

4. STOCK ASSESSMENT

There is no fishery independent stock assessment information to determine the stock status of porae. Biomass estimates have not been determined for porae.

5. STATUS OF THE STOCK

Estimates of current and reference biomass are not available. It is not known if recent catch levels or TACs are sustainable. The status of POR 1, 2 and 3 relative to B_{MSY} is unknown.

TACCs and reported landings for the 2012–13 fishing year are summarised in Table 4.

Table 4: Summary of TACCs (t) and reported landings (t) of porae for the most recent fishing year.

Fishstock	FMA	2012–13 Actual TACC	2012–13 Reported landings
POR 1 Auckland (East)	1	62	59
POR 2 Central (East)	2	18	9
POR 3 South east, Southland, sub-Antarctic, Challenger	3,4,5,6,7, 8 &9	2	0
POR 10 Kermadec	10	1	0
Total		83	67

PRAWN KILLER (PRK)

Ibacus alticrenatus

1. FISHERY SUMMARY

1.1 Commercial fisheries

Prawn killer (*Ibacus alticrenatus*) was introduced into the Quota Management System on 1 October 2007, with a combined TAC of 37.4 t and TACC of 36 t. There are no allowances for customary non-commercial or recreational fisheries, and 1.4 t was allowed for other sources of mortality. PRK is almost all taken as a bycatch in the scampi target trawl fishery in SCI 1 and SCI 2. Reported catches in PRK 1 have a maximum of 42 t in 1992–93. Landings in PRK 2 are minimal with a maximum of 8 t in 2002–03 (Table 1). Landings are likely to be less than total catches due to unreported discarding.

Table 1: TACCs and reported landings (t) of Prawn killer by Fishstock from 1990–91 until the present from CELR and CLR data. FMAs are shown as defined in 2007–08. [Continued on next page].

1.2 Recreational fisheries

There is no known non-commercial fishery for prawn killer.

1.3 Customary non-commercial fisheries

There is no known customary non-commercial fishery for prawn killer.

1.4 Illegal catch

No quantitative information is available on the level of illegal catch of prawn killer.

1.5 Other sources of mortality

There is no quantitative information on other sources of mortality, although analysis of benthic invertebrate samples and the distribution of trawl tows in the Bay of Plenty (PRK 1) suggests that this species is negatively affected by trawling.

2. BIOLOGY

Ibacus alticrenatus is widely distributed around the New Zealand coast, principally in depths of 80–300 m. Prawn killers are found on soft sediment seafloors, where they dig into the substrate and cover themselves with sediment.

There is not much information about growth and development of *I. alticrenatus* in New Zealand waters, but females are thought to mature at a carapace length of about 40 mm. Information from Australia suggests that this species has relatively low fecundity (1 700–14 800 eggs, increasing with size) and spawns annually. Larval development takes 4–6 months, an intermediate duration for a Scyllarid lobster. Females of other *Ibacus* species reach maturity about two years after settlement and longevity is suggested to be five years or more.

The following species might be caught as bycatch of the prawn killer catch – *Ibacus brucei*, *Antipodarctus aoteanus*, and *Scyllarus mawsoni* (which is thought to be rare).

3. STOCKS AND AREAS

For management purposes stock boundaries are based on those used for scampi. However, there is no biological information on stock structure, recruitment patterns, or other biological characteristics which might indicate stock boundaries.

4. STOCK ASSESSMENT

4.1 Estimates of fishery parameters and abundance

There are no estimates of fishery parameters or abundance for any prawn killer fishstock.

4.2 Biomass estimates

There are no biomass estimates for any prawn killer fishstock.

4.3 Yield estimates and projections

There are no estimates of *MCY* for any prawn killer fishstock.

There are no estimates of *CAY* for any prawn killer fishstock.

5. STATUS OF THE STOCKS

There are no estimates of reference or current biomass for any prawn killer fishstock. It is not known whether prawn killer stocks are at, above, or below a level that can produce *MSY*.

QUEEN SCALLOPS (QSC)

(*Zygochlamys delicatula*)

1. FISHERY SUMMARY

Queen scallops were introduced into the QMS in October 2002, with a current TACC (unchanged since its introduction) of 380 t and a 20 t allowance for other sources of fishing related mortality. The fishing year runs from the 1 October to the 30 September and the catch is reported in greenweight.

1.1 Commercial fisheries

The QSC 3 fishery initially developed in the 1984–85 fishing year; it is a small-scale fishery with only a few fishing vessels involved (Michael & Cranfield 2001). Queen scallops (*Zygochlamys delicatula*) are predominantly harvested commercially off the Otago coast, in depths of 130–200 m (predominately 150–200m) near the edge of the continental shelf. Reported landings from this fishery peaked at 711 t in the 1985–86 fishing year (not shown in the table below). Annual landings in most recent years have been less than 200 t, although this is more likely to be associated with economic, rather than biological, factors. The TACC was set in 2002 at a slightly higher level than recent landings but lower than the non-QMS competitive catch limit of 750 t which applied to FMA 3 from 1990–91. Reported landings of queen scallops are given in Table 1, and Figure 1 shows historical landings and the TACC for QSC 3. The queen scallop fishery is a trawl fishery using specialised gear (including a relatively light ‘tickler’ chain or wire to induce swimming) and the catch is sorted both mechanically and by hand (Michael & Cranfield 2001, R. Belton pers. comm.).

1.2 Recreational fisheries

There is no known recreational fishery for queen scallops.

1.3 Customary fisheries

There is no known customary harvest of queen scallops.

1.4 Illegal catch

Current levels of illegal harvest are not known.

1.5 Other sources of mortality

No quantitative estimate of other sources of mortality is available. Some grading of catch may occur (queen scallops may be returned to the sea) and an allowance of 20 t for potential mortality has been set within the current TAC.

QUEEN SCALLOPS (QSC)

Table 1: Reported landings (t greenweight) of queen scallops (QSC) by FMA, QMA and fishing year by all methods trawl and dredge) 1989–90 until the present day from Quota Management Reports (QMR), Monthly Harvest Returns (MHR) and Catch Effort Landing Returns (CELR landed and CELR estimated).

2. BIOLOGY

The New Zealand queen scallop (*Zygochlamys delicatula*) is also known as the southern queen scallop, southern fan scallop, and gem scallop. This small pectinid species is distributed on the outer continental shelf along the east coast of the South Island, from Kaikoura down to Macquarie Island. There are nine other species in the genus, none of which have attracted commercial interest, probably because of their small size. Similar species such as *Chlamys islandica* and *Chlamys varia* support important fisheries in other countries. New Zealand queen scallops are distributed from Kaikoura to the southern islands including the Snares, Bounty, Antipodes, and Macquarie Islands. There are no records of live queen scallops being caught north of Kaikoura, or on the west coast of the South Island.

A dredge survey off Otago in October 1983 showed that queen scallops were distributed in long patches orientated along the slope of the continental shelf. They were most abundant in depths beyond 130 m, on the plateau between the Taiaroa and Papanui Canyons, and south. North of the Taiaroa Canyon

catches diminished steadily towards the Karitane Canyon; few were caught north of the canyon. Only low numbers of queen scallops were caught in depths shallower than 110 m.

Juvenile queen scallops are frequently found attached to fragments of bryozoa and other biogenic debris, including the shells of other scallops and the dredge oyster. Height frequency distributions of samples show that the size composition of the population differs with area, and it is inferred that settlement probably varies spatially and temporally. The estimated 40–50 days larval life may result in queen scallop larvae being well mixed, both vertically and horizontally, in the water column. Predation of newly settled spat may also affect the pattern of recruitment and add to the variability in year class representation.

Estimates of growth for New Zealand queen scallops suggest that they become sexually mature at four years for males and five years for females. As length is slightly less than height, queen scallops are estimated to reach the minimum takeable size of 50 mm at about eight years. However, growth estimates are uncertain, with information from tagging studies suggesting that queen scallops enter the fishery much earlier, at three to five years.

3. STOCKS AND AREAS

Queen scallops are distributed throughout the QSC 3 area. From harvest records the scallops inhabit waters between 130 and 200 m depth. The extent to which various beds or populations are separate reproductively or functionally is not known.

4. STOCK ASSESSMENT

4.1 Estimates of fishery parameters and abundance

No estimates of fishery parameters or abundance are available at present.

4.2 Biomass estimates

A trawl survey, (Jiang et al 2005) carried out in February–April 2004, provided estimates of total and recruited biomass (shells at least 50 mm) available from the fished area of QSC 3, from Moeraki to just north of the Nuggets within the depth range 130 to 200 m, which covers 90% of the fished area within QSC 3 (Table 2). These estimates assumed that the efficiency of the survey trawl was 100%. However trawl efficiency is unlikely to be 100% and in other scallop fisheries can vary significantly depending on dredge and substrate type. Consequently estimates of current absolute biomass cannot be estimated. The Shellfish Working Group had concerns over methodology and conduct of the survey, and that the reported survey CVs may not be reliable.

Table 2: Estimated scallop biomass (recruit and pre-recruit) (t) in fished areas of QSC 3 February–April 2004.

Biomass Recruit (CV)	Biomass (CV) Pre-recruit	Total Biomass (CV)
1 950.8 (18.2)	363.6 (21.48)	2 314.4 (18.22)

4.3 Yield estimates and projections

As absolute biomass has not been estimated, *MCY* cannot be estimated

CAY cannot be estimated.

5. STATUS OF THE STOCKS

Stock structure assumptions

QSC 3 is assumed to be a single stock.

REDBAIT (RBT)*(Emmelichthys nitidus)***1. FISHERY SUMMARY****1.1 Commercial fisheries**

Redbait (*Emmelichthys nitidus*) was introduced to the Quota Management System on 1 October 2009, with a combined TAC of 5316 t and TACC of 5050 t. There are no allowances for customary non-commercial or recreational fisheries, and 266 t was allowed for other sources of mortality.

RBT is mainly taken as bycatch of the jack mackerel target trawl fishery, but also widely taken as bycatch of barracouta trawl tows, with some taken in the squid and hoki fisheries. A target fishery developed in the mid 2000s taking up to 11% of the catch of redbait in 2007–08. Reported total catches ranged from 2185 to 4308 tonnes during the 2000s, but declined across all QMAs and target fisheries in 2009–10 and 2010–11 to nearer 1000 t.

RBT 3 includes the southern fisheries for squid, and fisheries for Jack Mackerel on the Mernoo Bank and Chatham Rise, and accounted for most of the redbait landed in each year during the 1990s. From 2002–03 to 2009–10 however, the Jack Mackerel fishery on the west coast expanded into north and south Taranaki Bights, and catches from RBT 7 have exceeded those from RBT 3. Landings to RBT 1 have been small (less than 5 t) in most years, increasing slightly in the late 2000s.

TACs, allowances and TACCs from 1 October 2009 are reported in Table 1. Table 2 and Figure 1 show historical landings from 2001–02 to 2012–13, reported by newly defined QMAs.

Table 1: TACs, allowances and TACCs of redbait.

Fishstock	Other mortality	Customary non-commercial and recreational	TACC	TAC
RBT 1	1	0	19	20
RBT 3	115	0	2 190	2 305
RBT 7	150	0	2 841	2 991
RBT 10	0	0	0	0

1.2 Recreational fisheries

There is no known non-commercial fishery for redbait.

1.3 Customary non-commercial fisheries

There is no known customary non-commercial fishery for redbait.

1.4 Illegal catch

No quantitative information is available on the level of illegal catch of redbait.

1.5 Other sources of mortality

Taylor (2009) described up to 345 tonnes (but usually less than 200 t annually of redbait reported as discarded between 1988–89 to 2008–09).

2. BIOLOGY

Emmelichthys nitidus is a schooling, bathypelagic species that is closely related to rubyfish. It is widely distributed around New Zealand in depths from 85 to 500m. Juveniles are found at the surface and adults near the bottom in deeper waters, including seamounts.

There is not much information about growth and development of redbait in New Zealand. Offshore studies suggest regional differences in maximum size with a maximum age of 10 years in east Victoria and 7 years in Tasmania, where the maximum reported size of redbait

is 316 mm fork length. Spawning in Tasmania is thought to last 2-3 months during spring, with 50% mature at 24 cm FL and 2-3 years. Von Bertalanffy growth parameters of Tasmanian redbait for both sexes combined are given in Table 3.

Research data from New Zealand show that the maximum size of redbait here is about 420 mm FL, which is larger than most other regions where length of this species has been recorded, except South Africa. Recent validation of the ageing of the closely related rubyfish in New Zealand confirms maximum ages of 90+ suggesting that some emmelichthyids may be long-lived, so current estimates of growth and maximum age may not be reliable

Table 3 shows estimated biological parameters for redbait.

Table 3: Estimates of biological parameters for redbait. Growth is based on Australian studies (Welsford & Lyle 2003).

Fishstock	Estimate		Source

			NIWA (unpub. data)
<u>2. von Bertalanffy growth parameters</u>			
	Combined sexes		
RBT (Tasmania)	L_{∞}	k	t_0
	28.7	0.56	-0.36
			Welsford & Lyle (2003)

3. STOCKS AND AREAS

There is no information about stock structure, recruitment patterns, or other biological characteristics that would indicate stock boundaries. As the catch of redbait has been mainly (66%) from bycatch in the jack mackerel trawl fisheries, management boundaries have been set the same as those used for jack mackerel. Analysis of encounter rates suggests a north-south seasonal movement of redbait may occur at a spatial scale that is greater than QMAs.

4. STOCK ASSESSMENT

4.1 Estimates of fishery parameters and abundance

There are no estimates of fishery parameters or abundance for any redbait fishstock.

4.2 Biomass estimates

There are no biomass estimates for any redbait fishstock.

4.3 Yield estimates and projections

There are no yield estimates for any redbait fishstock.

5. STATUS OF THE STOCKS

There are no estimates of reference or current biomass for any redbait fishstock. It is not known whether redbait stocks are at, above, or below a level that can produce *MSY*.

RED COD (RCO)

(Pseudophycis bachus)

Hoka

1. FISHERY SUMMARY

1.1 Commercial fisheries

Red cod are targeted primarily by domestic trawlers in the depth range between 30 and 200 m and are also a bycatch of deepwater fisheries off the southeast and southwest coasts of the South Island. The domestic red cod fishery is seasonal, usually beginning in November and continuing to May or June, with peak catches around January and May. During spring and summer, red cod are caught inshore before the fishery moves into deeper water during winter. RCO entered the QMS in 1986

, Foreign vessel catches declined and were negligible by 1987-88. Reported annual catches by nation from 1970 to 1986-87 are given in Table 1.

Table 1: Reported annual catch (t) of red cod by nation from 1970 to 1986-87.

*FSU data.

§ Includes landings from unknown areas before 1986–87.

RED COD (RCO)

The bulk of reported landings are taken from RCO 3, in particular the Canterbury Bight and Banks Peninsula areas. The red cod fishery is characterised by large variations in catches between years. Research indicates that this interannual variation in catch is due to varied recruitment causing biomass fluctuations rather than a change in catchability. The RCO 3 TACC was reduced by 63% from the 1 October 2007 to 4600 t, with the TAC being set at 4930 t (customary, recreational and other sources of mortality were allocated 5, 95 and 230 t respectively). All RCO stocks fisheries have been put on to Schedule 2 of the Fisheries Act 1996. Schedule 2 allows that for certain “highly variable” stocks, the Total Annual Catch (TAC) can be increased within a fishing season. The base TAC is not changed by this process and the “in-season” TAC reverts to the original level at the end of each season. No RCO stocks have yet had an in-season increase.

Figure 1: Historical landings and TACC for the three main RCO stocks. From top to bottom: RCO2 (Central East) and RCO3 (South East Coast). [Figure continued on next page].

Figure 1 [Continued]: Historical landings and TACC for the three main RCO stocks. Above: RCO7 (Challenger).

1.2 Recreational fisheries

Recreational fishers take red cod, particularly on the east coast of the South Island. Results of five separate recreational fishing surveys are shown in Table 3.

Table 3: Estimated number and weight of red cod harvested by recreational fishers, by Fishstock and survey. Surveys were carried out in different years in the MAF Fisheries regions: South in 1991–92, Central in 1992–93, North in 1993–94 (Teirney *et al.* 1997) and nationally in 1996 (Bradford 1998) and 1999–00 (Boyd & Reilly 2002). Survey harvest is presented as a range to reflect the uncertainty in the estimates.

Fishstock	Survey	Number	CV %	Estimated harvest range (t)	Estimated point estimate (t)
1991–92					
RCO 3	South	104 000	16	90–120	-
RCO 7	South	1 000	-	0–5	-
1992–93					
RCO 2	Central	151 000	19	105–155	-
RCO 7	Central	1 100	34	5–15	-
1993–94					
RCO 1	North	9000	34	5–15	-
1996					
RCO 1	National	11 000	18	515	11
RCO 2	National	88 000	11	80–105	92
RCO 3	National	99 000	10	90–115	103
RCO 7	National	38 000	15	30–50	40
1999–00					
RCO 1	National	21 000	36	5–11	8
RCO 2	National	39 000	25	8–14	11
RCO 3	National	207 000	25	210–349	280
RCO 7	National	23 000	50	5–14	9

A key component of the process of estimating recreational harvest from diary surveys is determining the proportion of the population that fish. The Recreational Technical Working Group concluded that the harvest estimates from the diary surveys should be used only with the following qualifications: a) they may be very inaccurate; b) the 1996 and earlier surveys contain a methodological error; and c) the 2000 and 2001 estimates are implausibly high for many important fisheries. The 1999–00 harvest estimates for each Fishstock should be evaluated with reference to the coefficient of variation.

RED COD (RCO)

1.3 Customary non-commercial fisheries

Quantitative estimates of the current level of customary non-commercial catch are not available.

1.4 Illegal catch

Quantitative estimates of the level of illegal catch are not available.

1.5 Other sources of mortality

Processing limits on red cod are sometimes imposed to discourage fishers from landing red cod when the species cannot be processed or when markets are poor. This practice has encouraged dumping. Processing limits are currently less of a problem than in earlier years.

2. BIOLOGY

Red cod are a fast-growing, short-lived species with few fish in the commercial fishery older than six years. Red cod grow to about 25 cm total length (TL) in the first year, followed by annual growth increments of around 15, 10 and 5 cm. Growth of sexes is similar for the first two years, after which females tend to grow faster than males and reach a larger overall length. Sexual maturity ranges from 45 to 55 cm TL with a mean value of 52 cm TL for both sexes at an age of 2–3 years. M has been estimated to equal 0.76 for both sexes. In 1995, ageing of red cod was validated using marginal zone analysis.

In the 1989–90 to 1992–93 fishing years, 80% of the landings in RCO 3 were 2+ and 3+ fish (50–57 cm TL). The sex ratio of the commercial catch during this period was skewed towards females during November (F:M ratio of 3.4:1) with the ratio tending to even out by May. Schools are generally comprised of single age cohorts rather than a mix of age classes.

Spawning in red cod varies with latitude, with spawning occurring later at higher latitudes. In the Canterbury Bight, spawning occurs from August to October. No definite spawning grounds have been identified on the southeast coast, but there is some evidence that red cod spawn in deeper water (300–750 m). Running ripe fish were caught on the Puysegur Bank in 600 m during the Southland trawl survey in February 1994. Juvenile red cod are found in offshore waters after the spawning period; however, no nursery grounds are known for this species.

Red cod are seasonally abundant, with schools appearing in the Canterbury Bight and Banks Peninsula area around November. These schools are feeding aggregations and are not found in these waters after about June. Catch data indicates that they move into deeper water after this time. Recruitment is highly variable resulting in large variations in catches between years.

Biological parameters relevant to the stock assessment are shown in Table 4.

Table 4: Estimates of biological parameters for red cod.

3. STOCKS AND AREAS

The number of red cod stocks is unknown. There is no information about stock structure, recruitment patterns, or other biological characteristics that would indicate stock boundaries.

4. STOCK ASSESSMENT

No recent stock assessments have been carried out on any red cod stocks. Previous assessments were undertaken, however, these are now outdated. Details appear in previous versions of the Plenary report.

Trawl survey biomass estimates are available from one *Tangaroa* and four *Kaharoa* time series (Table 5, Figures 2, 3 and 4). In 2001, the Inshore FAWG recommended that the summer east coast South Island trawl survey be discontinued due to the extreme variability in the catchability of the target species. The winter series was re-instated in 2007 and was run initially for three consecutive years. The East and West Coast South Island trawl surveys track both biomass and population length structure.

4.1 Biomass estimates

The biomass of red cod from core strata (30–400m) of the East Coast South Island trawl survey was largely unchanged between 2007 and 2009 and remained low relative to the period between 1991 and 1994. In contrast the biomass in 2012 was more than six-fold greater than in 2009 and was predominantly contributed by 1+ fish. The proportion of pre-recruited biomass has varied greatly among surveys ranging from 7 to 59% of the total biomass and in 2012 it was the highest ever at 59%, reflecting the strong 1+ cohort. The proportion of juvenile biomass (based on the length-at-50% maturity) has also varied greatly among surveys from 27 to 80% and in 2012 it was 70% (Figure 3).

The additional red cod biomass captured in the 10–30 m depth range accounted for only 4% and 2% of the biomass in the core plus shallow strata (10–400 m) for 2007 and 2012 respectively, indicating that in terms of biomass, it is informative but, probably not essential to monitor the shallow strata for red cod. Further, the addition of the 10–30 m depth range had little effect on the shape of the length frequency distributions (Figure 4).

The distribution of red cod hot spots varies, but overall this species is consistently well represented over the entire survey area, most commonly from 30 m to about 300 m, but is also found in waters shallower than 30 m.

Figure 2: Biomass trends $\pm 95\%$ CI (estimated from survey CVs assuming a lognormal distribution) and the time series mean (dotted line) from the West Coast South Island trawl survey

RED COD (RCO)

Figure 3: Red cod total biomass and 95% confidence intervals for the all ECSI winter surveys in core strata (30–400 m), and core plus shallow strata (10–400 m) for species found in less than 30 m in 2007 and 2012.

Figure 4: Red cod juvenile and adult biomass for ECSI winter surveys in core strata (30–400 m), where juvenile is below and adult is equal to or above length at which 50% of fish are mature.

4.2 Length frequency distributions

The size distributions of red cod in each of the nine core strata (30–400 m) of the East Coast South Island trawl survey surveys are similar and are generally characterised by a 0+ mode (10–20 cm), 1+ mode (30–40 cm), and a less defined right hand tail comprised predominantly of 2+ and 3+ fish. The 1996 to 2009 surveys show poor recruitment of 1+ fish compared to earlier surveys. The 2012 1+ cohort is the largest of all nine surveys. Red cod on the ECSI (Figure 5), sampled during these surveys, are generally smaller than those from Southland (Figure 6) suggesting that this area may be an important nursery ground for juvenile red cod.

4.3 Other factors

There have been large fluctuations in red cod abundance and landings, particularly on the east and the west coast of the South Island. This causes problems for the fishers who rely on red cod, and creates additional pressure on the ACE system. Changes in catch rates of red cod, combined with the recovery of other quota species since the introduction of the QMS, has resulted in a catch mix for which some fishers do not have the appropriate quota holdings. Bycatch species while targeting red cod are stargazer, red gurnard, elephant fish, rig, school shark, blue cod, groper and tarakihi. As a result, effort targeting red cod may be reduced to alleviate bycatch problems, despite the availability of red cod quota.

RED COD (RCO)

Table 5: Relative biomass indices (t) and coefficients of variation (CV) for red cod for east coast South Island (ECSI) - summer and winter, west coast South Island (WCSI), and Southland survey areas*. Biomass estimates for ECSI in 1991 have been adjusted to allow for non-sampled strata (7 & 9 equivalent to current strata 13, 16 and 17). The sum of pre-recruit and recruited biomass values do not always match the total biomass for the earlier surveys because at several stations length frequencies were not measured, affecting the biomass calculations for length intervals. – , not measured; NA, not applicable. Recruited is defined as the size-at-recruitment to the fishery (40 cm).

Region	Fishstock	Year	Trip number	Total Biomass estimate	CV (%)	Total Biomass estimate	CV (%)	Pre-recruit	CV (%)	Pre-recruit	CV (%)	Recruited	CV (%)	Recruited	CV (%)

*Assuming areal availability, vertical availability and vulnerability equal 1.0. Biomass is only estimated outside 10 m depth except for COM9901 and CMP0001. Note: because trawl survey biomass estimates are indices, comparisons between different seasons (e.g., summer and winter ECSI) are not valid

RED COD (RCO)

Figure 5: Scaled length frequency distributions for red cod in core strata (30–400 m) for all nine of the ECSI winter surveys. The length distribution is also shown in the 10–30 m depth strata for the 2007 and 2012 surveys overlaid (not stacked) in light grey. Population estimates are for the core strata only, in thousands of fish. Scales are the same for males, females and unsexed..

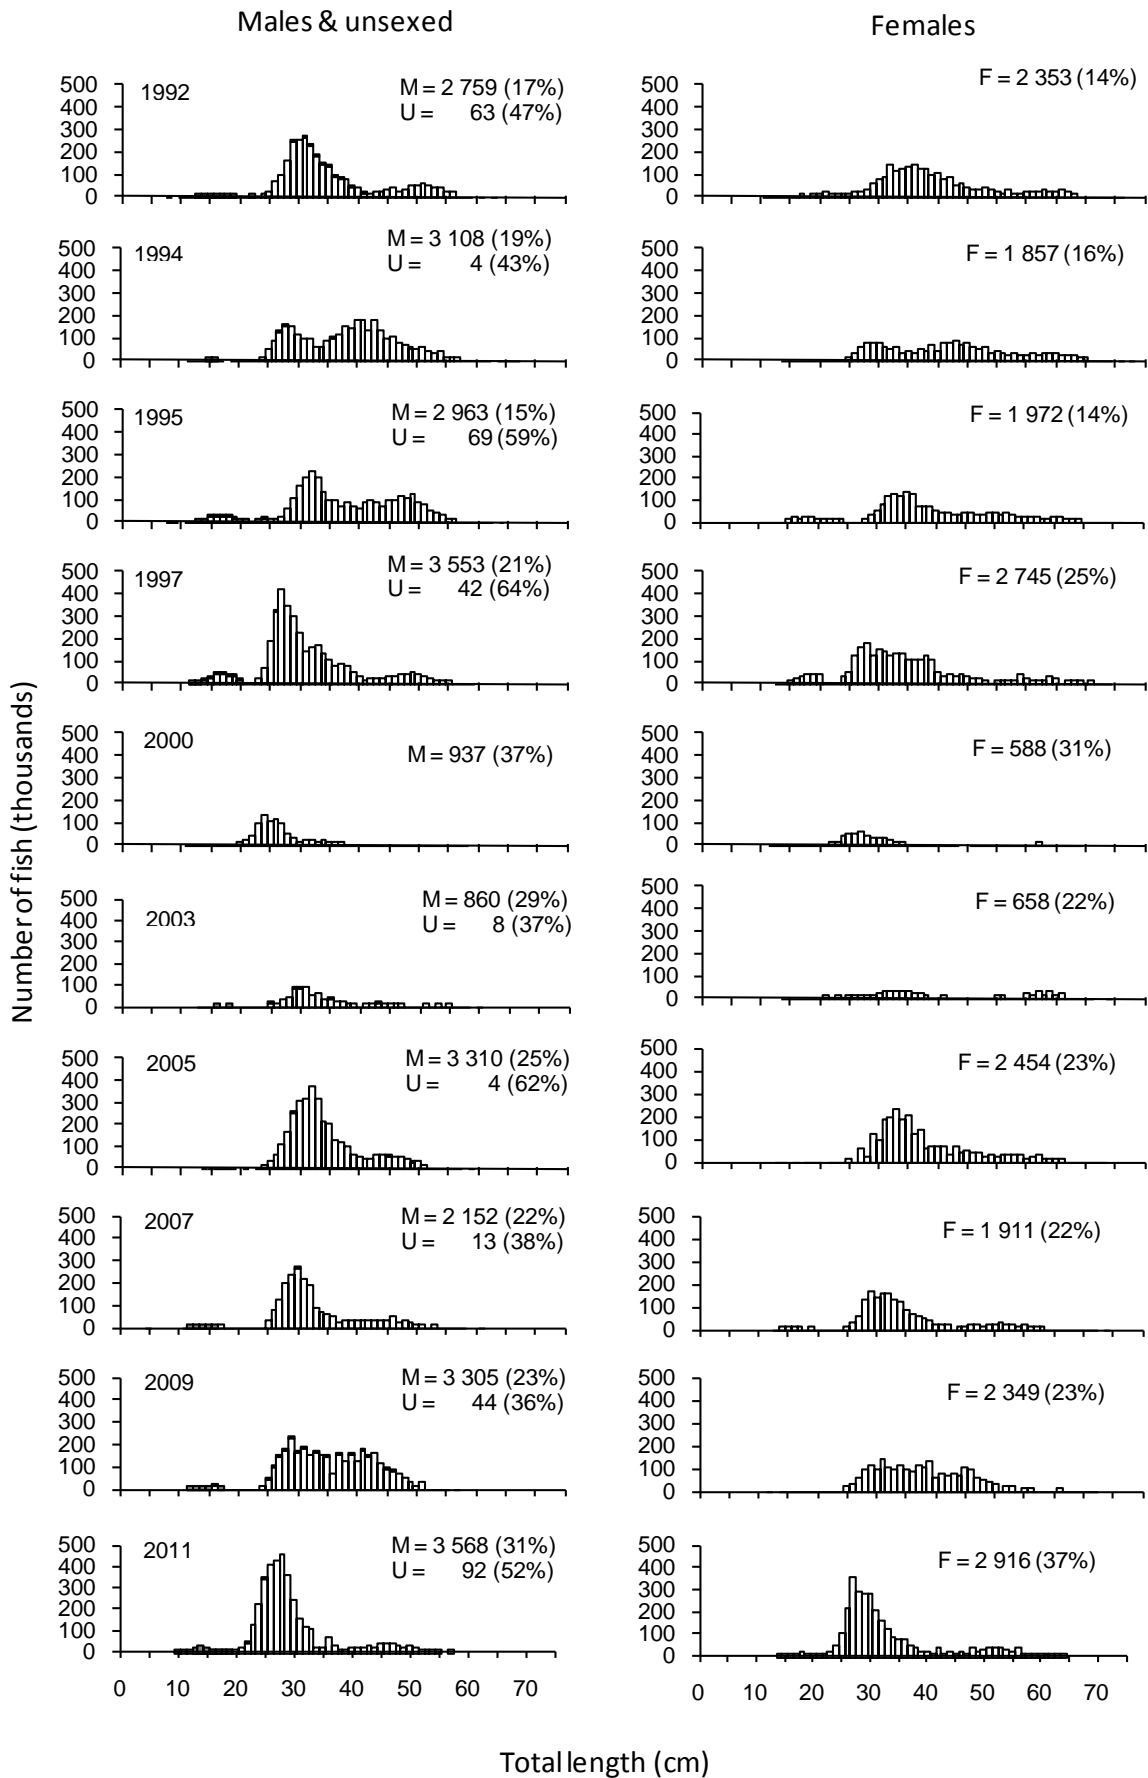

Figure 6: Scaled length frequency distributions for red cod in 30–400 m, for all WCSI surveys. M, males; F, females; U, unsexed (CV%) (Stevenson 2012).

5. STATUS OF THE STOCKS

Yearly fluctuations in red cod catch reflect changes in recruitment. Trawl surveys and catch sampling of red cod have shown that the fishery is based almost exclusively on two and three year old fish and is highly dependent on recruitment success.

The disparity between the TACC and reported landings indicates that the TACC is not generally attained. At the time of the introduction to the QMS, the rationale for introducing and retaining a TACC of this magnitude was to provide the fishing industry with the flexibility to capitalise on years when red cod are plentiful.

RCO 3

Stock Status	
Year of Most Recent Assessment	2009
Assessment Runs Presented	-
Reference Points	Target: <i>MSY</i> -compatible proxy based on the East Coast South Island trawl survey (to be determined) Soft Limit: 50% of target Hard Limit: 25% of target
Status in relation to Target	Unknown
Status in relation to Limits	Soft limit: Unknown Hard Limit: Unknown

Historical Stock Status Trajectory and Current Status

East Coast South Island survey biomass (points) commercial catch (red dashed line) and TACC (blue dashed line) for the period 1990 to 2009. Horizontal line dashed is the mean biomass index, 1992-2009.

Fishery and Stock Trends	
Recent Trend in Biomass or Proxy	Both catch and survey biomass have declined substantially since the mid 1990s.
Recent Trend in Fishing Mortality or Proxy	Unknown

Other Abundance Indices	-
Trends in Other Relevant Indicators or Variables	From 1991 to 1994 large recruitment pulses were seen in the survey catch. The most recent three surveys (2007, 2008 and 2009) have not detected any significant recruitment.

Projections and Prognosis	
Stock Projections or Prognosis	Biomass estimates from the recently re-instated winter East Coast South Island since 2007 confirm that biomass is low relative to the 1990s.
Probability of Current Catch or TACC causing decline below Limits	Soft Limit: Unknown Hard Limit: Unknown
Assessment Methodology and Evaluation	
Assessment Type	Level 2: Trawl survey
Assessment Method	Accepted biomass index
Assessment Dates	Latest assessment: 2011 Next assessment: Unknown
Overall assessment quality rank	1 – High Quality. The Southern Inshore Working Group agreed that the East Coast South Island index was a credible measure of red cod biomass.
Main data inputs (rank)	Trawl survey biomass estimates and length frequency analysis 1 – High Quality

-

Fishery Interactions
Red cod are landed as bycatch in barracouta, flatfish, squid and tarakihi bottom trawl fisheries and ling, school shark, spiny dogfish, rig, tarakihi and moki setnet fisheries. Incidental captures of seabirds occur.

RCO 7

Stock Structure Assumptions

Stock boundaries are unknown, but for the purpose of this summary RCO 7 is considered to be a single management unit.

Stock Status	
Year of Most Recent Assessment	2009 West Coast South Island trawl survey
Reference Points	Target: <i>MSY</i> -compatible proxy based on the West Coast South Island trawl survey (to be determined) Soft Limit: 50% of target Hard Limit: 25% of target
Status in relation to Target	Unknown
Status in relation to Limits	Soft limit: Unknown Hard Limit: Unlikely (< 40%) to be below
Fishery and Stock Trends	
Trend in Biomass or Proxy	Biomass indices have been increasing from a series low in 2000, with the current 2009 index above the long-term mean.
Trend in Fishing Mortality or Proxy	Unknown

RED COD (RCO)

Historical survey biomass, Catch and TACC Trajectories

West Coast South Island survey biomass (points) commercial catch (red line) and TACC (blue line) for the period 1990 to 2009. Horizontal line dashed represents the mean biomass index, 1992–2011.

Other Abundance Indices	-
Trends in Other Relevant Indicator or Variables	Length frequency analysis from the West Coast South Island trawl survey in 2009 show a wide distribution of male fish in 2009.

Projections and Prognosis

Stock Projections or Prognosis	Based on the broad size composition in the survey, high biomass levels are expected to persist in the short-term.
Probability of Current Catch / TACC causing decline below Limits	Soft Limit: Unknown Hard Limit: Unknown

Assessment Methodology

Assessment Type	Level 2: Partial Quantitative Stock Assessment	
Assessment Method	Evaluation of survey biomass trends and length frequencies.

Fishery Interactions

Red cod are primarily taken in conjunction with the following QMS species: stargazer, red gurnard, tarakihi and various other species in the West Coast South Island target bottom trawl fishery. Smooth skates are caught as a bycatch in this fishery, and the biomass index for smooth skates in the west coast trawl survey has declined substantially since 1997. There may be similar concerns for rough skates but the evidence is less conclusive. Incidental captures of seabirds occur.

Yield estimates, TACCs and reported landings for the 2012–13 fishing year are summarised in Table 6.

Table 6: Summary of yield estimates (t), TACCs (t) and reported landings (t) of red cod for the most recent fishing year. *MCY(1)* from eY_{AV} method, *MCY(2)* from MIAEL method (range only given).

Fishstock	FMA		<i>MCY(1)</i>	<i>MCY(2)</i>	2012–13 Actual TACC	2012–13 Reported landings

RED CRAB (CHC)*(Chaceon bicolor)***1. FISHERY SUMMARY****1.1 Commercial fisheries**

The red crab (*Chaceon bicolor*) was introduced into the Quota Management System on 1 April 2004 with a combined TAC of 48 t and TACC of 48 t (Table 1). There are no allowances for customary, recreational or other sources of mortality. The fishing year is from 1 April to 31 March and commercial catches are measured in greenweight. There were no commercial catches of this crab until 2001–02, when landings of about 1.5 t were reported. *C. bicolor*, along with several other deepwater crabs, was the focus of an exploratory fishing (potting) permit during 2000–02. Significant quantities have been found in the Bay of Plenty, east of Great Barrier Island, and east of Northland. The other region fished was the east coast of the North Island south of East Cape, where smaller catches were periodically reported (Table 1). Figure 1 shows the historical landings and TACC for CHC 1.

There are two species of *Chaceon* known from New Zealand waters. *C. yaldwyni* is almost indistinguishable from *C. bicolor*, but is a very rarely caught species from the eastern Chatham Rise (fewer than five specimens have ever been caught).

Table 1: TACCs and reported landings (t) of red crab by Fishstock from 2001–02 to present from CELR and CLR data. There have never been any reported landings of red crab from CHC 3–10, so these are not tabulated; although CHC 3–9 have TACCs of 4 t.

Fishstock	CHC 1		CHC 2		Total	
	Landings	TACC	Landings	TACC	Landings	
2001–02	1.132	-	0.065	-	1.27	-
2002–03	0.604	-	0	-	0.604	-
2003–04	0	-	0.009	-	0.009	-
2004–05	0	10	0.215	10	0.215	48
2005–06	0.021	10	0	10	0.021	48
2006–07	0.017	10	0.004	10	0.021	48

2008–09	0	10	0.068	10	0.068	48
2009–10	0.985	10	0.071	10	1.056	48
2010–11	5.532	10	0.420	10	5.970	48
2011–12	0	10	0.011	10	0.043	48
2012–13	0	10	0.01	10	0.01	48

*In 2001–02 77.5 kg were reportedly landed, but the FMA is not recorded. This amount is included in the total landings for that year.

1.2 Recreational fisheries

There are no known records of recreational use of this crab.

Figure 1: Historical landings and TACC for CHC 1 (Auckland East). QMA data from 2004–05 to present.

1.3 Customary non-commercial fisheries

There are no known records of customary use of this crab.

1.4 Illegal catch

There is no known illegal catch of this crab.

1.5 Other sources of mortality

There is no quantitative information on other sources of mortality, although this crab is often taken as a bycatch in orange roughy fishing.

2. BIOLOGY

C. bicolor is a very large, purple and tan to yellowy tan coloured crab that reaches at least 192 mm carapace width (CW). It is found on and north of the Chatham Rise, and particularly along the east coast north of Hawkes Bay to North Cape. It has been found on both hard and soft substrates, but is considered to be a burrowing crab, living in soft sediments. It has been recorded from depths between 800 and 1100 m around New Zealand, and between 275 and 1620 m elsewhere in the Pacific.

C. bicolor was previously referred to as *C.* (sometimes *Geryon*) *quinquedens* and belongs to the family Geryonidae which has an almost world-wide distribution. There is no information on its reproduction, age, growth, or natural mortality in New Zealand waters—which may or may not be similar to the same or similar *Chaceon* species elsewhere.

Geryonid crabs such as *C. bicolor* tend to show partial sex segregation, females being in shallower water than males. Small crabs are usually found in deeper water than the adults, as a result of juvenile settlement in deep water. There can be both seasonal and ontogenetic movements between depth zones.

Females carry a single clutch of eggs during the winter, which hatch the following summer. Clutch size increases with female size, and egg numbers are of the order of 100 000 to 400 000. The eggs are small (0.5–0.6 mm diameter), suggesting a relatively long larval life, probably resulting in widespread dispersal. Off Western Australia, however, *C. bicolor* females may be ovigerous at any time of the year. One study off Western Australia found that the lengths at 50% maturity were 90.5 mm and 94 mm carapace length (CL) for females and males respectively.

Pot catches usually yield a very biased sex ratio favouring males, which may be due to the fact that ovigerous females remain buried in the substrate during incubation.

3. STOCKS AND AREAS

For management purposes stock boundaries are based on QMAs, however, there is currently no biological or fishery information which could be used to identify biological stock boundaries.

4. STOCK ASSESSMENT

4.1 Estimates of fishery parameters and abundance

There are no estimates of fishery parameters or abundance for any red crab fishstock.

4.2 Biomass estimates

There are no biomass estimates for any red crab fishstock.

4.3 Yield estimates and projections

There are no estimates of *MCY* for any red crab fishstock.

There are no estimates of *CAY* for any red crab fishstock.

5. STATUS OF THE STOCKS

There are no estimates of reference or current biomass for any red crab fishstock.

RED GURNARD (GUR)*(Chelidonichthys kumu)*

Kumukumu

**1. FISHERY SUMMARY****1.1 Commercial fisheries**

Red gurnard are a major bycatch of inshore trawl fisheries in most areas of New Zealand, including fisheries for red cod in the southern regions and flatfish on the west coast of the South Island (WCSI) and in Tasman Bay. They are also directly targeted in some areas e.g. GUR2. Some minor target fisheries for red gurnard are known in Pegasus Bay, off Mahia and off the west coast South Island. Red gurnard is also a minor bycatch in the jack mackerel trawl fishery in the South Taranaki Bight. Up to 15% of the total red gurnard catch is taken by bottom longline and setnet.

Red gurnard was introduced into the Quota Management System (QMS) in 1986. The 1986 TACCs were based on 1984 landings for Southland and 1983 landings for other regions. TACCs for GUR 3 and 7 were increased by 76 t (14%) and 137 t (20%) respectively for the 1991–92 fishing year under the Adaptive Management Programme (AMP), to 600 t in GUR 3 and to 815 t in GUR 7. The GUR 7 TACC was reduced to 678t, in 1997–98. For the 2009–10 fishing season, the TACC in GUR 7 was increased from 681 t to 715 t, including an allocation of 10 t for customary, 20 t for recreational use, and 14 t allocation for other sources of mortality. The GUR 7 TACC was further increased to 785t in October 2012. The TACC for GUR 3 was increased, by 300 t (50%) to 900 t, for the 1996–97 fishing year under the AMP, but decreased to 800 t in 2002–03. For the 2009–10 fishing season, the TACC for GUR 3 was increased from 800 t to 900 t, with allocations of 3 t, 5 t, and 45 t for customary, recreational, and other sources of mortality respectively. The GUR 3 TACC was increased to 1100 t in October 2012. This TACC can be seen in Table 1 along with all current allowances, TACCs and TACs. All AMP programmes ended on 30 September 2009.

RED GURNARD (GUR)

Recent reported landings and actual TACCs by Fishstock are shown in Table 2, while Figure 1 depicts the historical landings and TACC values for the main GUR stocks.

Annual landings of GUR 1 have been relatively stable since 1986–87, generally ranging between 900 and 1300 t; substantially lower than the 2287 t TACC. About 60% of the GUR 1 total is taken from FMA 1, as a bycatch of a number of fisheries including inshore trawl fisheries for snapper, John Dory and tarakihi. The remaining 40% is taken from FMA 9, mainly as a bycatch of the snapper and trevally inshore trawl fisheries.

Table 2: Reported landings (t) of red gurnard by Fishstock from 1983–84 to 2011–12 and actual TACCs (t) from 1986–87 to 2012–13. The QMS data is from 1986–present.

*FSU data.

GUR 2 landings have fluctuated within the range of 400–8530 t since 1991–92, typically well below the TACC. In addition to the target fishery, red gurnard are taken as a bycatch of the tarakihi, trevally and snapper inshore trawl fisheries.

GUR 3 landings regularly exceeded the TACC between 1988–89 and 1995–96. Ageing of fish collected during the east coast South Island trawl (ECSI) surveys suggests that there were 1 or 2 relatively strong year classes moving through the fishery, which may help explain the overcatches. GUR 3 has been consistently overcaught since 2004.

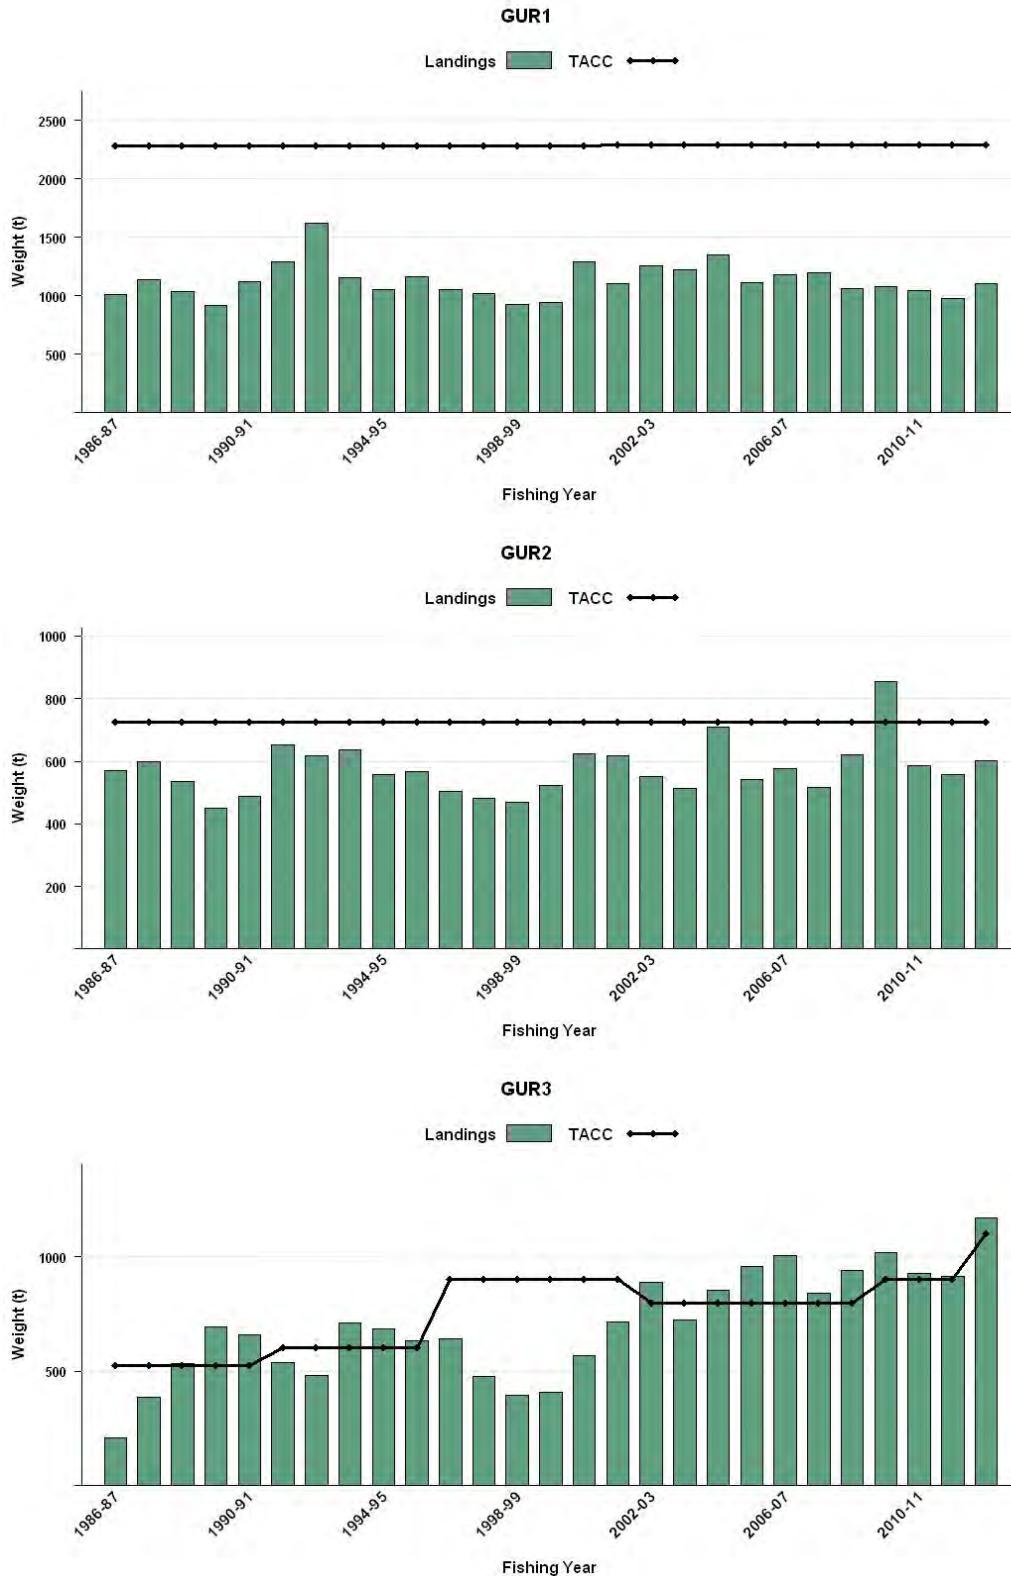

Figure 1: Historical landings and TACCs for the five main GUR stocks. From top to bottom: GUR 1 (Auckland East), GUR 2 (Central East) [Continued on next page].

RED GURNARD (GUR)

Figure 1 [Continued]: Historical landings and TACCs for the five main GUR stocks. From top to bottom: GUR 3 (South East Coast), GUR 7 (Challenger) and GUR 8 (Central Egmont).

GUR 7 landings declined steadily from 761 t in 1992–93, to 309 t in 1997–98, but then increased to a peak of 793 t in 2002–03. They then generally declined to 2010–11, followed by an increased to 2012/13. Landings in GUR 8 have remained well below the levels of the TACC since 1986–87.

1.2 Recreational fisheries

Red gurnard is, by virtue of its wide distribution in harbours and shallow coastal waters, an important recreational species. It is often taken by fishers targeting snapper and tarakihi, particularly around the North Island. The allowances within the TAC for each Fishstock are shown in table 1.

1.2.1 Management controls

The main methods used to manage recreational harvests of red gurnard are minimum legal size limits (MLS), method restrictions and daily bag limits. Fishers can take up to 20 GUR as part of their combined daily bag limit and the MLS is 25 cm.

1.2.2 Estimates of recreational harvest

Recreational catch estimates are given in Table 3. There are two broad approaches to estimating recreational fisheries harvest: the use of onsite or access point methods where fishers are surveyed or counted at the point of fishing or access to their fishing activity; and, offsite methods where some form of post-event interview and/or diary are used to collect data from fishers.

The first estimates of recreational harvest for red gurnard were calculated using an offsite approach, the offsite regional telephone and diary survey approach. Estimates for 1996 came from a national telephone and diary survey (Bradford 1998). Another national telephone and diary survey was carried out in 2000 (Boyd & Reilly 2005) and a rolling replacement of diarists in 2001 (Boyd & Reilly 2004 allowed estimates for a further year (population scaling ratios and mean weights were not re-estimated in 2001).

The harvest estimates provided by these telephone diary surveys are no longer considered reliable for various reasons. With the early telephone/diary method, fishers were recruited to fill in diaries by way of a telephone survey that also estimates the proportion of the population that is eligible (likely to fish). A “soft refusal” bias in the eligibility proportion arises if interviewees who do not wish to co-operate falsely state that they never fish. The proportion of eligible fishers in the population (and, hence, the harvest) is thereby under-estimated. Pilot studies for the 2000 telephone/diary survey suggested that this effect could occur when recreational fishing was established as the subject of the interview at the outset. Another equally serious cause of bias in telephone/diary surveys was that diarists who did not immediately record their day’s catch after a trip sometimes overstated their catch or the number of trips made. There is some indirect evidence that this may have occurred in all the telephone/diary surveys (Wright et al 2004).

Table 3: Recreational harvest estimates for red gurnard stocks. The telephone/diary surveys and earlier aerial-access surveys ran from December to November but are denoted by the January calendar year. The surveys since 2010 have run through the October to September fishing year but are denoted by the January calendar year. Mean fish weights were obtained from boat ramp surveys (for the telephone/diary and panel survey harvest estimates).

Stock	Year	Method	Number of fish	Total weight (t)	CV
<u>GUR 1</u>	1996	Telephone/diary	262, 000	108	0.07
	2000	Telephone/diary	465,000	223	0.16

<u>GUR 2</u>	1996	Telephone/diary	38, 000	16	0.18
	2000	Telephone/diary	209, 000	127	0.37
	2012	Panel survey	64, 292	37	0.20
<u>GUR 3</u>	1996	Telephone/diary	1, 000	-	-
	2000	Telephone/diary	11,000	5	0.70
	2012	Panel survey	4, 635	2	0.62
<u>GUR 7</u>	1996	Telephone/diary	26, 000	12	0.15
	2000	Telephone/diary	36,000	11	0.23
	2012	Panel survey	23, 692	12	0.24
<u>GUR 8</u>	1996	Telephone/diary	67, 000	28	0.15
	2000	Telephone/diary	99,000	40	0.36
	2012	Panel survey	93, 058	46	0.23

The recreational harvest estimates provided by the 2000 and 2001 telephone diary surveys are thought to be implausibly high for many species, which led to the development of an alternative maximum count aerial-access onsite method that provides a more direct means of estimating recreational harvests for suitable fisheries. The maximum count aerial-access approach combines data collected concurrently from two sources: a creel survey of recreational fishers returning to a subsample of ramps throughout the day; and an aerial survey count of vessels observed to be fishing at the approximate time of peak fishing effort on the same day. The ratio of the aerial count in a particular area to the number of interviewed parties who claimed to have fished in that area at the time of the overflight was used to scale up harvests observed at surveyed ramps, to estimate harvest taken by all fishers returning to all ramps. The methodology is further described by Hartill et al (2007).

This aerial-access method was first employed and optimised to estimate snapper harvests in the Hauraki Gulf in 2003–04. It was then extended to survey the wider SNA 1 fishery in 2004–05 and to provide estimates for other species, including red gurnard (FMA 1 only for GUR).

RED GURNARD (GUR)

In response to the cost and scale challenges associated with onsite methods, in particular the difficulties in sampling other than trailer boat fisheries, offsite approaches to estimating recreational fisheries harvest have been revisited. This led to the development and implementation of a national panel survey for the 2011–12 fishing year. The panel survey used face-to-face interviews of a random sample of New Zealand households to recruit a panel of fishers and non-fishers for a full year. The panel members were contacted regularly about their fishing activities and catch information collected in standardised phone interviews. Note that the national panel survey estimate does not include harvest taken on recreational charter vessels, or recreational harvest taken under s111 general approvals.

1.3 Customary non-commercial fisheries

Red gurnard is an important species for customary non-commercial fishing interests, by virtue of its wide distribution in shallow coastal waters. However, no quantitative estimates of customary non-commercial catch are currently available.

1.4 Illegal catch

No quantitative information is available.

1.5 Other sources of mortality

No quantitative information is available.

2. BIOLOGY

Gurnard growth rate varies with location, and females grow faster and are usually larger at age than males. Maximum age (A_{MAX}) is about 16 years and maximum size is 55+ cm. Red gurnard reach sexual maturity at an age of 2–3 years and a fork length (FL) of about 23 cm, after which the growth rate slows. An analysis of the age and growth of red gurnard in FMA 7 revealed that young fish 1–4 years old tend to be most common in Tasman and Golden Bays. Three to six year old fish are found on the inshore areas of the West coast South Island and the older fish are predominantly found further offshore (Lyon & Horn 2011).

M was estimated using the equation $M = \log_e 100/\text{maximum age}$, where maximum age is the age to which 1% of the population survives in an unexploited stock. Samples from the ECSI suggested an A_{MAX} of about 16 years for males and 13 years for females, giving estimates for M of 0.29 and 0.35 respectively. Samples from the WCSI indicate an A_{MAX} of about 15 years for both sexes, giving an estimate of 0.31 for M . These samples were not from virgin populations, so M may be overestimated.

Red gurnard have a long spawning period which extends through spring and summer with a peak in early summer. In the Hauraki Gulf, ripe adults can be found throughout the year. Spawning grounds appear to be widespread, although perhaps localised over the inner and central shelf. Egg and larval development takes place in surface waters, and there is a period of at least eight days before feeding starts. Small juveniles (under 15 cm FL) are often caught in shallow harbours, but rarely in commercial trawls.

Biological parameters relevant to the stock assessment are shown in Table 4.

Table 4: Estimates of biological parameters for red gurnard.

3. STOCKS AND AREAS

There are no data that would alter the current stock boundaries. No information is available on stock separation of red gurnard. For GUR 3 the Working Group noted that spatial information from the CPUE analyses indicated that separate stocks or sub-stocks may exist between the East and South coasts of the South Island.

4. STOCK ASSESSMENT

4.1 Biomass estimates

Relative abundance indices have been obtained from trawl surveys of the Bay of Plenty, west coast North Island and Hauraki Gulf within the GUR 1 Fishstock and the South Island west coast and Tasman/Golden Bays combined (GUR 7) (Table 5).

In the 1990s, red gurnard biomass in the core strata (30–400 m) of the East Coast South Island trawl survey averaged 422 t and this increased nearly four-fold to an average of 1541 t from 2007 to 2012. There has been no trend since 2007 with biomass being relatively stable. The proportion of pre-recruited biomass in the core strata has varied greatly among surveys, but is generally low – ranging from 2% to 20% and in 2012 it was 11%. Similarly, the proportion of juvenile biomass (based on the length-at-50% maturity) is almost zero or close to it for all surveys. These observations indicate that this survey may not be indexing sub-mature gurnard.

The additional red gurnard biomass captured in the 10–30 m depth range accounted for 29% and 52% of the biomass in the core plus shallow strata (10–400 m) for 2007 and 2012 respectively, indicating that in terms of biomass or number of fish, it is essential to monitor the shallow strata for red gurnard. Further, the addition of the 10–30 m depth range had a significant effect on the shape of the length frequency distributions, with the appearance of a strong 1+ cohort in 2012, otherwise poorly represented in the core strata. The sex ratio also favours females in the shallow strata, whereas the sex ratio is at parity in the core strata.

The distribution of red gurnard hot spots varies, but overall this species is consistently well represented over the entire survey area from 10 to 100 m, but is most abundant in the shallow 10 to 30 m.

RED GURNARD (GUR)

The relative total biomass index (pre-recruit and recruited fish) calculated for the entire GUR7 stock (West coast and Tasman Bay combined) was stable from 1992 to 2000, was relatively low in 2003 and has steadily increased from 2003 to 2013 (Figure 2).

Figure 2: Gurnard biomass trends \pm 95% CI (estimated from survey CVs assuming a lognormal distribution) and the time series mean (dotted line) from the West Coast South Island trawl surveys.

4.2 Length frequency distributions

Length frequency trends for the West Coast South Island red gurnard catch are presented in Figure 3. These data show that there were substantial numbers of 20–25 cm fish in 1997 and 2000. Fish of this size did not appear in large numbers in 2003 or 2005 but high numbers were caught again in 2007, 2009 and 2013.

For the East Coast South Island trawl surveys, the size distributions of red gurnard in the four core strata (30–400 m) appear to have become more consistent since the reinstatement of this survey in 2007 and as the biomass has increased (Figure 4). Over this period, the gurnard length distributions have been characterised by a single mode representing multiple age classes ranging from 1+ to 12. The length frequency distributions in the shallow plus core strata (10–400 m) are only represented by the 2007 and 2012 surveys, with both survey years being dominated by the main core strata along with indications of a 1+ mode distinct from the older aged cohorts. The proportion of pre-recruited biomass in the core plus shallow strata is also greater than that of the core strata alone (i.e., 24% compared to 20% in 2007, and 21% compared to 11% in 2012), a reflection of the larger numbers of smaller red gurnard found in the shallow strata, particularly in 2012.

Table 5: Relative biomass indices (t) and coefficients of variation (CV) for gurnard for east coast South Island (ECSI) - summer and winter, west coast South Island (WCSI) and the Stewart-Snares Island survey areas*. Biomass estimates for ECSI in 1991 have been adjusted to allow for non-sampled strata (7 & 9 equivalent to current strata 13, 16 and 17). The sum of pre-recruit and recruited biomass values do not always match the total biomass for the earlier surveys because at several stations length frequencies were not measured, affecting the biomass calculations for length intervals. – , not measured; NA, not applicable. Recruited is defined as the size-at-recruitment to the fishery (30 cm). [Continued on next page].

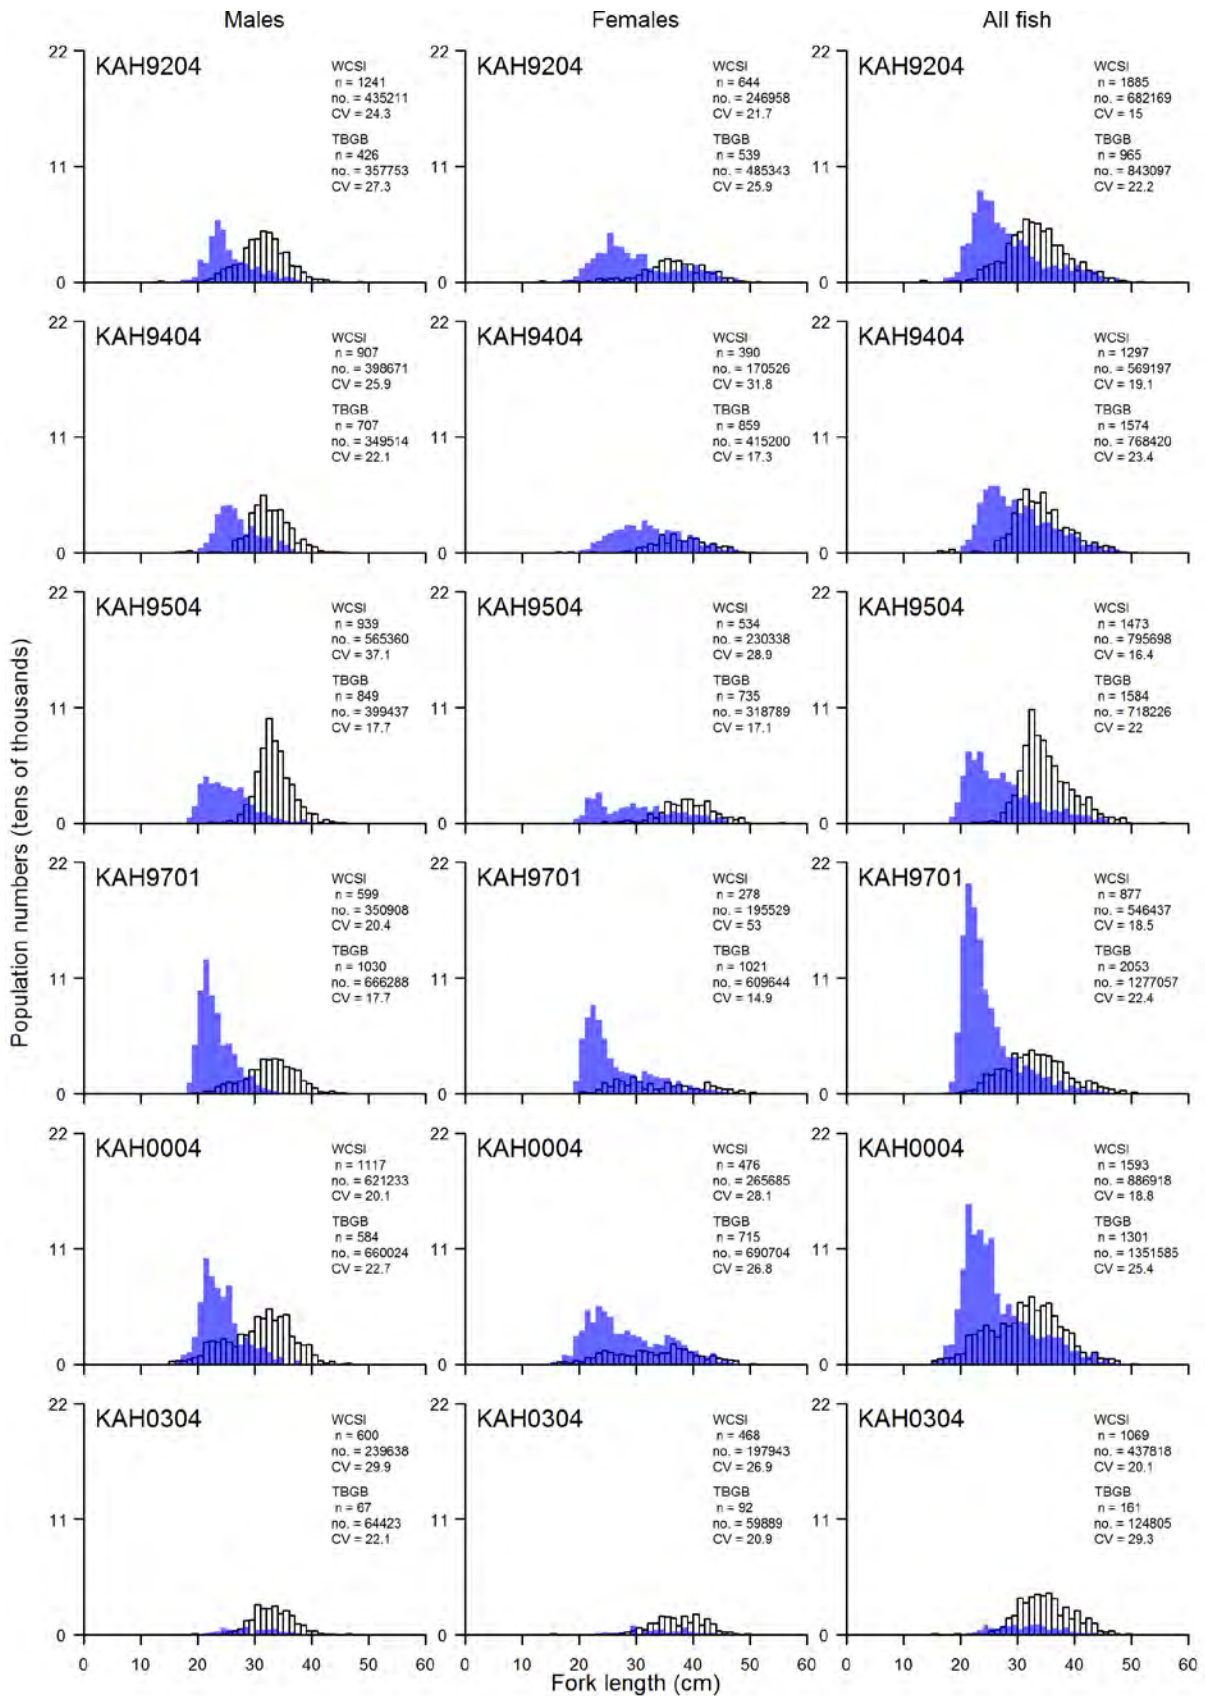

Figure 3: Scaled length frequency distributions for red gurnard in 30–400 m, for all WCSI trawl surveys. M, males; F, females; (CV%). The blue bars represent the TBGB area of the survey; the white bars represent WCSI.

RED GURNARD (GUR)

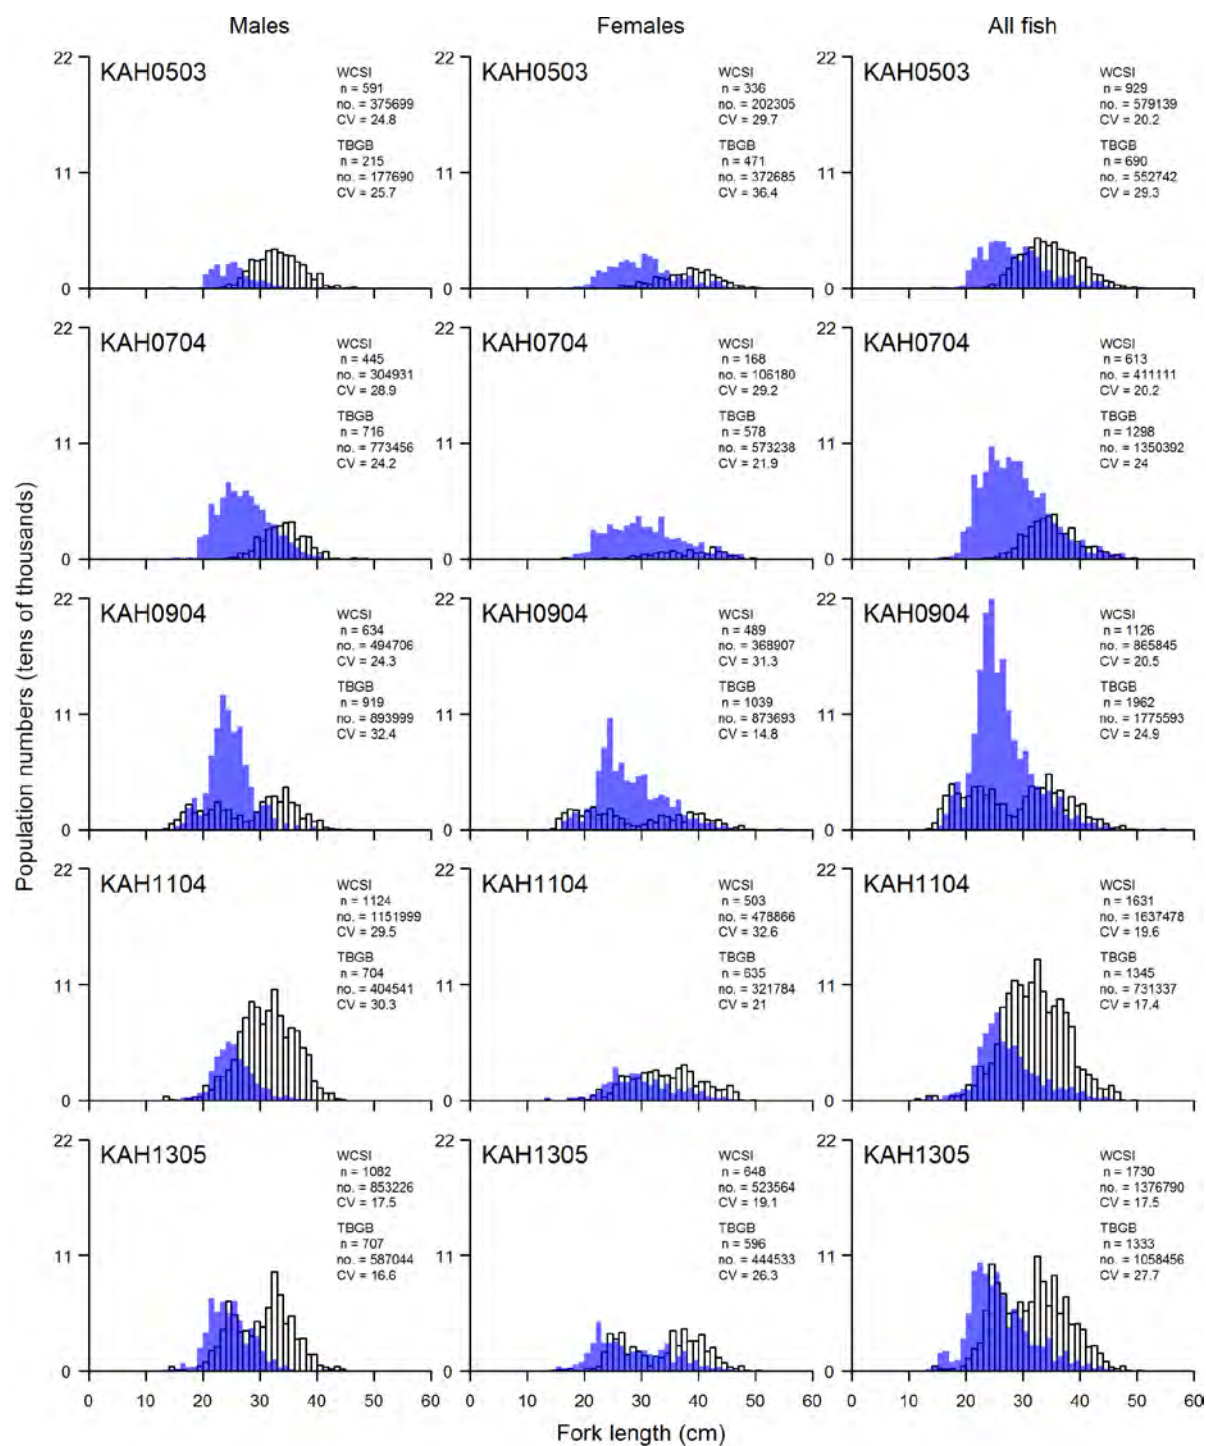

Figure 3 continued: Scaled length frequency distributions for red gurnard in 30–400 m, for all WCSI trawl surveys. M, males; F, females; (CV%). The blue bars represent the TBGB area of the survey; the white bars represent WCSI.

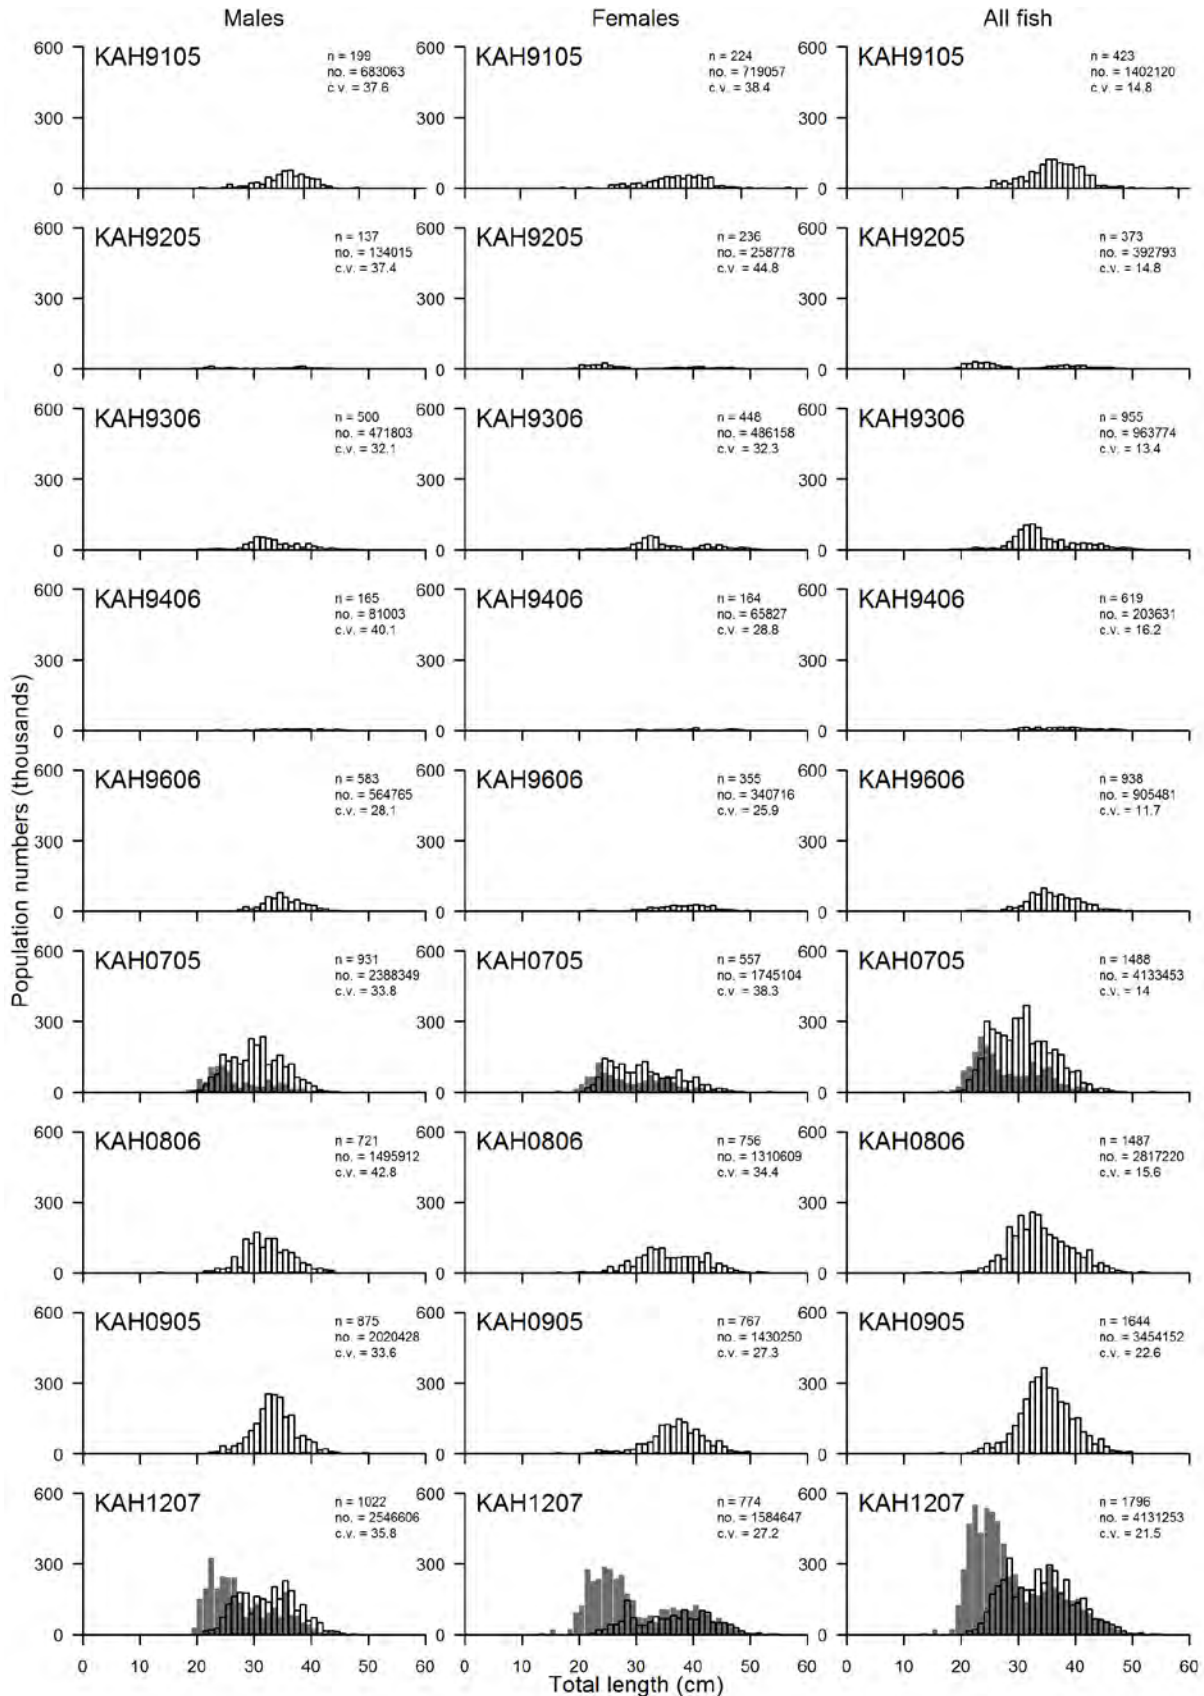

Figure 4: Scaled length frequency distributions for gurnard in core strata (30–400 m) for all nine of the ECSI winter surveys. The length distribution is also shown in the 10–30 m depth strata for the 2007 and 2012 surveys overlaid (not stacked) in light grey. Population estimates are for the core strata only, in thousands of fish. Scales are the same for males, females and unsexed.

4.3 CPUE Analyses

GUR 1

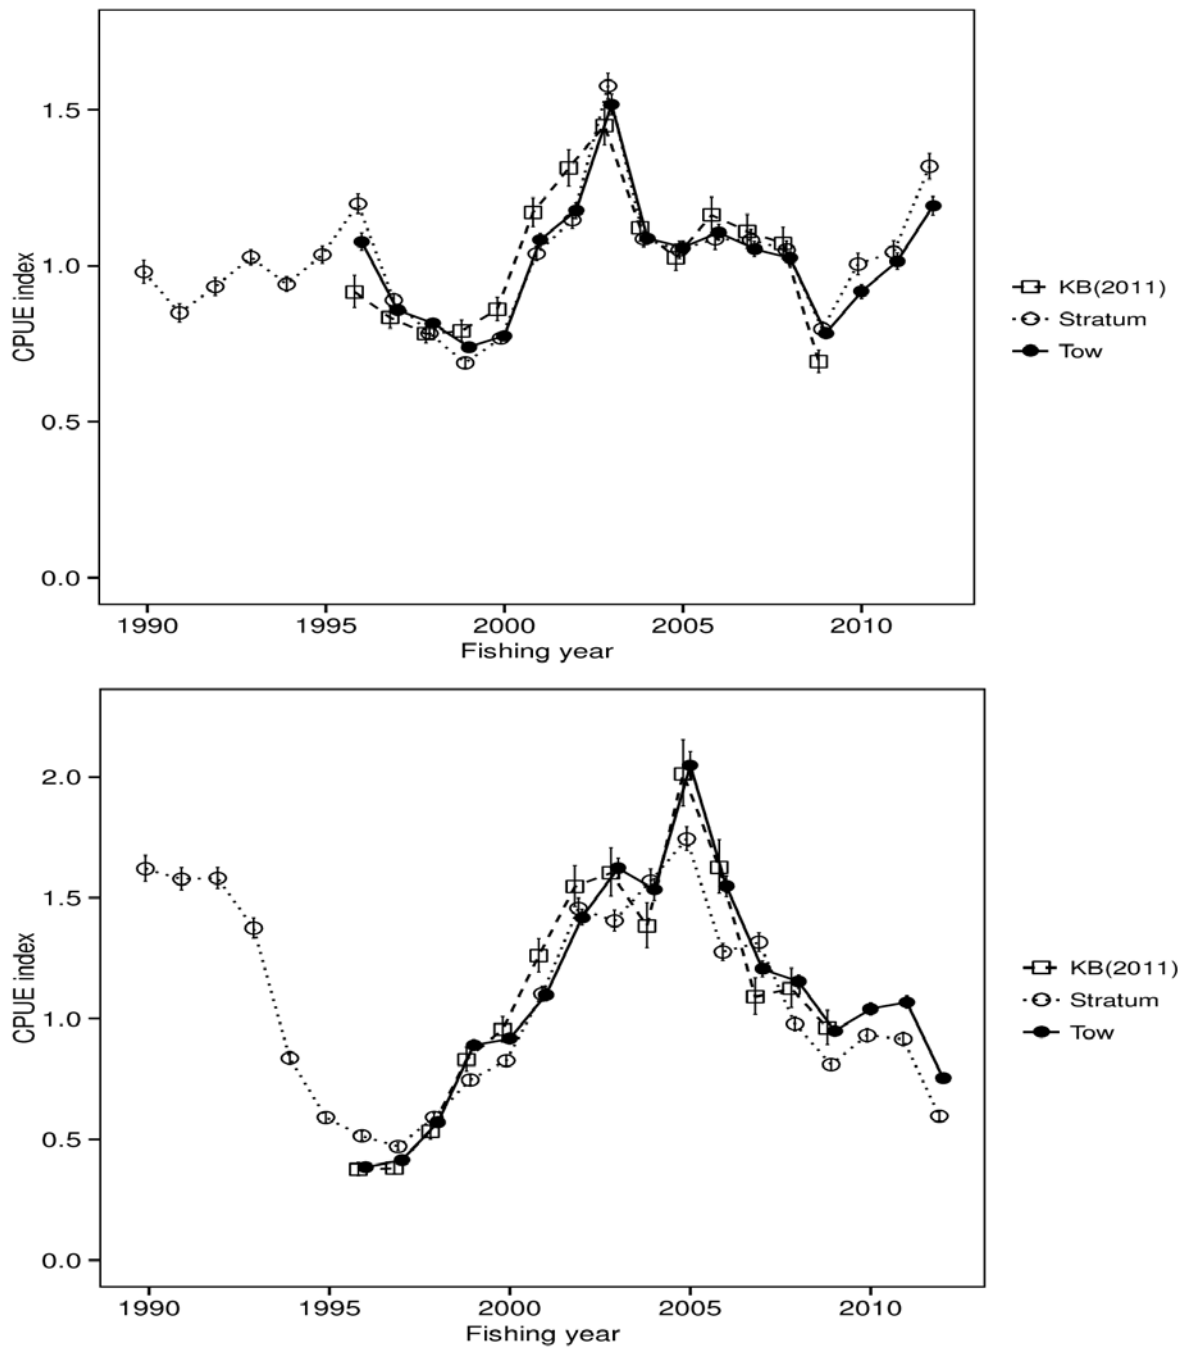

Figure 5: Comparison of indices for GUR 1W (upper) and GUR 1E (lower) for bottom trawl based on TCEPR/TCE format data (tow) with a longer time series (stratum) that includes CELR data, and also with the previous analysis (Kendrick & Bentley 2011) Error bars are ± 1 s.e.

Figure 6: Comparison of indices for GUR 1 BoP for bottom trawl based on TCEPR/ TCE format data (tow) with a longer time series (stratum) that includes CELR data, and also with the previous analysis (Kendrick & Bentley 2011). Error bars are ± 1 s.e.

In 2012, Kendrick & Bentley (in prep) updated CPUE analyses for GUR 1W, GUR 1E, and GUR 1BP (Figures 5 and 6). For each substock, positive catches from single bottom trawl targeted at gurnard, snapper, trevally, tarakihi or John dory were standardised using data from selected core vessels.

The analyses were based on tow based CPUE reported on TCEPR and TCER forms because adequate time series are available in the northern inshore trawl fisheries from 1995–96. Stratum based analyses were also done for each substock that included CELR forms and aggregated data to a common vessel-date-target-area stratum (Table 6). This produced longer time series (from 1989–90) that give an historical perspective to the recent trends.

For each CPUE analysis the suitability of alternative assumptions about the distributions of GLM errors were examined. The distribution which produced the lowest AIC when fitted using a simple, preliminary model was chosen.

Table 6: Details of CPUE analyses for each substock of red gurnard in GUR 1.

	Criteria (trips, years)	Core vessels		Error distribution
		Number	Catch (%)	
<u>West coast</u>				
Tow	3, 3	34	93	Gamma
Stratum	3, 3	46	97	Weibull
<u>East coast</u>				
Tow	3, 3	41	98	log-logistic
Stratum	3, 3	64	96	log-logistic
<u>Bay of Plenty</u>				
Tow	3, 3	44	98	log-logistic
Stratum	3, 3	61	97	weibull

All three series show strong cyclical fluctuations with a strong recovery from low levels reached between 1995 and 1999 to a peak in the early 2000s followed by a subsequent decline but with bigger

RED GURNARD (GUR)

magnitude changes evident in the east coast substock than in the other two. The series also differ with respect to the specific years for the nadir and the peak, as well as the nature of the trajectory after the peak in the early 2000s; each is currently near the mean for the series, but the west coast is increasing, while East coast and Bay of Plenty series are in a downward phase.

The Working Group accepted the tow-based series for ongoing monitoring of each substock.

GUR 2

GUR 2 is monitored using the bottom trawl fishery targeting gurnard, snapper or trevally and standardised CPUE is based on a model of positive catches from statistical areas 011–015.

In 2014, Kendrick & Bentley (in prep) updated CPUE analyses for GUR 2 (Figure 4) using a gamma error distribution, and a core fleet of 60 vessels that had completed at least five trips per year in at least five years. Landings were allocated to daily aggregated effort using methods described by Langley (2014) to improve the comparability between the data collected from two different statutory reporting forms (CELR and TCER). The model adjusted for the recent positive influences of shifts in duration, vessel, an area x month interaction term, and target species, and accounted for 51% of the variance in catch. A shorter time series based on TCEPR and TCER format data available since 2007–08, and analysed at tow by tow resolution closely resembles the mixed form series for the years in common (Figure 7).

The series describes a long gradual decline to the lowest point of the series in 2005–06 that is followed by six years of relative stability and the suggestion of an increase in the most recent year to above the mean for the series. An alternative analysis based on bycatch from the deeper tarakihi fishery also corroborated the overall trends.

Figure 7: Comparison of standardised catch per unit effort (CPUE) indices for GUR 2 from bottom trawling targeting gurnard, snapper and trevally (GUR.BT.MIX) combined over all form types, and more recently from data based on TCEPR/ TCE (tow) format data only (Kendrick & Bentley, in prep. Both series are scaled relative the geometric mean of the years they have in common. Fishing years are labelled according to the second calendar year e.g 1990 = 1989–90. In both standardisation models a gamma error distribution was assumed.

Chapman and Robson estimates of total mortality (Z) for GUR 2, based on the age composition of bottom trawl landings in 2009–10, were 0.518 (SE = 0.0159, CV=3.1%) and 0.632 (0.0196, 3.1),

depending on whether the age of full recruitment was 2 or 3 years (Parker & Fu 2012). Assuming an instantaneous rate of natural mortality of 0.307, fishing mortality was estimated to be 0.189 or 0.303.

Although it was not possible to produce reliable estimates of spawner biomass per recruit based targets of F (due to unreliable estimates of growth rate and size at maturity), estimates of F from this study were either lower or approximately equal to the estimate of natural mortality (depending on the age at full recruitment assumed). Assuming that the fishery is sampling the age structure of the population, and given that catches and standardised CPUE have been reasonably constant over the last decade, these results suggest that GUR 2 was not over-exploited in 2010, and that the stock is likely to be at or above B_{MSY} .

Establishing B_{MSY} compatible reference points

The Working Group accepted mean CPUE from the (BT(MIX)) model for the period 1990–91 to 2009–10 as an B_{MSY} -compatible proxy for GUR 2. The Working Group accepted the default Harvest Strategy Standard definitions that the Soft and Hard Limits would be one half and one quarter the target, respectively.

GUR 3

In 2012, the Working Group accepted two standardised CPUE series for GUR 3 with both series based on the bycatch of red gurnard in bottom trawl fisheries defined by different target species combinations from fishing within the inshore statistical areas of GUR3 (018, 020, 022,024, 026, 025, 030). The BT(MIX) index included fishing effort targeting RCO, STA, BAR, TAR, GUR while the BT(FLA) index was comprised of FLA target trawls only (Starr & Kendrick 2013).

In 2014, the two CPUE analyses were updated with data from 1989/90 to 2012/13 (Langley 2014). The analysis also included several refinements to improve the comparability between the data collected from two statutory reporting forms (CELR and TCER) which collect data at different levels of detail (daily and by tow), including the approach used to apportion red gurnard landed catches from individual fishing trips to the associated fishing effort records and the daily aggregation of fishing effort. These refinements in data processing resulted in no appreciable change in the resulting CPUE indices for the corresponding period.

The 2014 CPUE analyses used the equivalent model formulations to the previous analyses (dependent and explanatory variables and Weibull error structure)(Starr & Kendrick 2013). The time-series of CPUE indices from the two fisheries are very similar. The indices were at a relatively low level in 1997/98-1999/2000 and increased steadily to a peak during 2007/08-2010/11 (Fig. 5). Both sets of indices were lower than the peak level in 2010/11 and 2012/13, although the indices remained well above the longer term average level from the entire time-series (Figure 8).

The longer term trends in the CPUE indices are comparable to the increase in estimates of recruited biomass (defined as fish at least 30 cm T.L.) from the time series of winter ECSI inshore trawl surveys (Figure8).

Establishing B_{MSY} compatible reference points

In 2012, BT(MIX+FLA), the mean of the BT(MIX) and BT(FLA) series in each year, was accepted by the Working Group as the series for monitoring GUR3. These fisheries cover different aspects of gurnard distribution, both by depth and spatially, but still have very similar trajectories, providing some confidence that these series are likely to be tracking abundance. The mean from 1997–98 to 1999–00 of BT(MIX+FLA) was selected as the Soft Limit because it was a well-defined low point in the series, along with the observations that both catch and CPUE increased simultaneously from that point. The Working Group accepted the default Harvest Strategy Standard definitions that the target “ B_{MSY} compatible proxy” for GUR 3 would be twice the Soft Limit and the Hard Limit was one-half the Soft Limit.

RED GURNARD (GUR)

Figure 8: Standardised CPUE indices for two east coast South Island bottom trawl fisheries [BT(MIX) and BT(FLA)] compared to trawl survey estimates of recruited (≥ 30 cm T.L.) biomass for red gurnard from the winter ECSI inshore trawl survey for two survey areas (30-400 m and 10-400 m). Error bars show $\pm 95\%$ confidence intervals.

GUR 7

In 2011, the Working Group accepted four standardised CPUE series for GUR 7 based on the bycatch of red gurnard in bottom trawl fisheries defined by different target species combinations in two different sub-areas: west coast South Island (statistical areas 033, 034, 035, 036) and Tasman Bay/Golden Bay and Cook Strait (038, 017, 018 and 039) (Kendrick et al 2011). The four CPUE data sets are defined in Table 7.

Table 7: Names and descriptions of the four red gurnard GUR 7 bottom trawl CPUE series accepted by the Working Group in 2011. Also shown is the error distribution that had the best fit to the distribution of standardised residuals for the fitted model.

Name	Code	Statistical areas	Target species	Best distribution
GUR 7 WCSI mixed target species	WCSL_BT_MIX	033, 034, 035, 036	RCO, STA, BAR, TAR, WAR	Lognormal
GUR 7 WCSI flatfish target	WCSL_BT_FL A	033, 034, 035, 036	FLA	Lognormal
GUR 7 Tasman Bay/Golden Bay flatfish target	TBGB_BT_FL A	038, 017	FLA, RCO	Lognormal
GUR 7 Tasman Bay/Golden Bay and Cook Strait mixed target	TBCS_BT_FL A	038, 017, 018, 039	BAR, TAR, WAR	Lognormal

In 2014, these four CPUE analyses were updated with data from 1989/90 to 2012/13 (Langley 2014). These analyses also included several refinements to improve the comparability between the data collected from two statutory reporting forms (CELR and TCER) which collect data at different levels of detail (daily and by tow), including the approach used to apportion red gurnard landed catches from individual fishing trips to the associated fishing effort records and the daily aggregation of fishing effort. These refinements in data processing resulted in no appreciable change in the resulting CPUE indices for the corresponding period.

The 2014 CPUE analyses used the equivalent model formulations to the previous analyses (dependent and explanatory variables and error structure) (Kendrick et al 2011).

The two sets of CPUE indices from the west coast South Island fisheries show similar cyclical trends with relatively high CPUE indices during 1990/91-1991/92 and 2001/02-2003/04 and relatively low CPUE indices in 1993/94-1999/2000 and 2006/07-2010/11 (Figure 9). The CPUE indices steadily increased from 2009/10 to a relatively high level in 2012/13.

The trawl survey biomass estimates of recruited (at least 30 cm T.L.) red gurnard from the west coast component of the WCSI Trawl Survey do not exhibit the same cyclical trends as seen in the CPUE indices; however, the high biomass estimates from the two recent trawl surveys (2011 and 2013) are consistent with the recent increase in the CPUE indices (Figure 9).

Figure 9: Comparison of the lognormal indices from two independent CPUE series for GUR 7 from the inshore WCSI trawl fisheries (statistical areas 033, 034, 035, and 036); a) WCSI_BT_FL A: bottom trawl, target FLA; b) WCSI_BT_MIX: bottom trawl, target, BAR, TAR, WAR, STA, RCO. Trawl survey biomass estimates of recruited (≥ 30 cm T.L.) red gurnard from the WC area of the WCSI inshore trawl survey are also presented. The vertical bars represent the associated 95% confidence intervals.

The trends in CPUE indices from the northern areas (TB/GB and Cook Strait) of GUR 7 are considerably different from the WCSI CPUE indices (Figure 10 compared to Figure 9). For the northern areas, the TBCS_BT_MIX CPUE indices during 1989/90-2005/06 tended to follow the trend in the TBGB_BT_FL A CPUE indices with a lag of about 2 years (Figure 10). However, in the subsequent years (2006/07-2012/13) the two sets of indices have shown divergent trends. There was a marked decline in the level of red gurnard catch from the TBCS mixed trawl fishery between 2006/07 to 2012/13. In 2010-11-2012/13 that mixed fishery accounted for a very small proportion of the total GUR 7 catch. Since 2007/08, there was also a marked shift in the spatial distribution of fishing effort in the TBCS fishery with a reduction in the proportion of fishing effort within the areas of higher red gurnard catch rates and a shift towards trawling in deeper waters (Langley 2014). On that basis, the 2014 Working Group rejected the TBCS_BT_MIX CPUE index as an index of abundance for GUR 7.

The TBGB_BT_FL A CPUE indices were relatively low during 1995/96-1998/99, increased in 1999/2000 and remained relatively stable at about that level until 2007/2008. From 2007/08 to 2012/13, the CPUE indices have tended to increase, although the recent increase may be partly attributable to an increase in the proportion of fishing effort within the shallower areas of TB/GB that

RED GURNARD (GUR)

tend to have a higher catch rate of red gurnard (Langley 2014). Because of this effect and the lack of correspondence with the TBGB WCSI trawl survey results (see next paragraph), the 2014 WG discounted the utility of this CPUE series.

The time series of trawl biomass estimates of recruited (at least 30 cm T.L.) red gurnard from the Tasman Bay/Golden Bay strata of the Challenger survey varies considerably among surveys and the biomass estimates are not well correlated with the corresponding CPUE indices (TBGB_BT_FL A) (Figure 10). There is no persistent trend in the trawl survey biomass estimates and recent (2011 and 2013) biomass estimates are at about the average level for the time series.

Figure 10: Comparison of the lognormal indices from two independent CPUE series for GUR 7 ; a) TBGB_BT_FL A: bottom trawl in statistical areas 38, and 17, target FLA or RCO ; b) TBGB_BT_MIX: bottom trawl in statistical areas 38, 39, 17 and 18, target, BAR, TAR, WAR. Trawl survey biomass estimates of recruited (≥ 30 cm T.L.) red gurnard from the TBGB area of the Challenger inshore trawl survey are also presented. The vertical bars represent the associated 95% confidence intervals.

Establishing B_{MSY} compatible reference points

In 2014, a composite series (WCSI_BT_MIX+FLA), which averaged the WCSI_BT_MIX and WCSI_BT_FL A series in each year, was accepted by the Working Group as the CPUE series for monitoring GUR7. However, because there was poor agreement between the CPUE series and the relative biomass series from the WCSI trawl survey (also accepted as an index of abundance for GUR7), the Working Group agreed to use both series to develop B_{MSY} proxy reference points for GUR 7, with one based on the mean WCSI_BT_MIX+FLA series and the other based on relative abundance from the west coast component of the WCSI trawl survey. In each case, the mean of the indices for the complete series (beginning in 1989/90 for the CPUE series and 1992 for trawl survey series; the CPUE series ends in 2012/13 and the trawl survey series ends with the 2013 biomass index) was chosen as a “ B_{MSY} compatible proxy” for GUR 7. The Working Group accepted the default Harvest Strategy Standard definitions that the Soft and Hard Limits would be one half and one quarter the target, respectively.

4.4 Other factors

Red gurnard is a major bycatch of target fisheries for several different species, such as snapper and flatfish. The target species may differ between areas and seasons. The recorded landings are influenced directly by changes in the fishing patterns of fisheries for these target species and indirectly by the abundance of these target species. Some target fishing for gurnard also occurs.

5. STATUS OF THE STOCKS

Stock Structure Assumptions

For the purpose of this summary GUR 1 is considered to be a single stock with three sub-stocks.

- **GUR 1W**

Stock Status	
Year of Most Recent Assessment	2013
Assessment Runs Presented	Standardised CPUE
Reference Points	Target: B_{MSY} -compatible proxy based on the mean CPUE from 1994–95 to 2011–12 of the bottom trawl GUR 1 west (tow) series Soft Limit: 50% of target Hard Limit: 25% of target Overfishing threshold: F_{MSY}
Status in relation to Target	About as Likely as Not (40–60%) to be at or above B_{MSY}
Status in relation to Limits	Soft Limit: Unlikely (< 40%) Hard Limit: Very Unlikely (< 10%)
Status in relation to Overfishing	Overfishing is Unlikely (< 40%) to be occurring

Historical Stock Status Trajectory and Current Status

Comparison of standardised CPUE for red gurnard in GUR 1W from models of catch rate in successful bottom trawl trips done for tow by tow data from 1995–96 (± 2 s.e.) and at stratum level including CELR data from 1989–90 (Kendrick & Bentley in prep. Also shown is the trajectory of total landed GUR 1 from the sub-stock area. The two CPUE series have been scaled to the mean of each series for the years in common. Horizontal lines represent the target and soft and hard limits.

RED GURNARD (GUR)

Annual relative exploitation rate for red gurnard in the GUR 1 west coast sub-stock.

Fishery and Stock Trends	
Recent Trend in Biomass or Proxy	The CPUE index cycles over a 4–8 year period consistent with the dynamics of a short lived species with variable recruitment. CPUE suggests that stock size has fluctuated around the long-term average since 1995–96, recovering from lows in 1998–99 and 2008–09. The CPUE has increased since 2008–09 and in 2011–12 was slightly above the long-term mean.
Recent Trend in Fishing intensity or Proxy	Relative exploitation rate has fluctuated without trend since 1991–92.
Other Abundance Indices	The GUR 1West (stratum) series is slightly longer than the GUR 1 West (tow) series, but has a similar trend for the overlapping period.
Trends in Other Relevant Indicators or Variables	-
Projections and Prognosis	
Stock Projections or Prognosis	Without information on recruitment, it is not possible to predict how the stock is going to respond in the next few years.
Probability of Current Catch or TACC causing Biomass to remain below or to decline below Limits	Soft Limit: Unlikely if the catch remains at current levels Hard Limit: Unlikely if the catch remains at current levels Unknown whether catch at the level of the TACC would cause decline below both the soft and hard Limits
Probability of Current Catch or TACC causing Overfishing to continue or to commence	Probability of TACC causing overfishing to occur or commence: Unlikely if the catch remains at current levels Unknown whether catch at the level of the TACC would cause overfishing
Assessment Methodology and Evaluation	
Assessment Type	Level 2 - Partial quantitative stock assessment
Assessment Method	Standardised CPUE based on positive catches from bottom trawl
Assessment Dates	Latest assessment: 2013 Next assessment: 2018
Overall assessment quality rank	1 – High Quality
Main data inputs (rank)	- Catch and effort data 1 – High Quality
Data not used (rank)	N/A
Changes to Model Structure and Assumptions	The accepted CPUE index is now a tow based index, rather than trip-stratum based.
Major Sources of Uncertainty	-

Qualifying Comments

As the red gurnard fishery in FMAs 1 and 9 has a long history, it is difficult to infer stock status from recent abundance trends. The abundance of all three sub-stocks appears to be cyclical, probably in response to recruitment variation, and in two sub-stocks trends are currently downward. This makes it difficult to predict future trends without recruitment information. Given that the catch levels observed from 1986–87 to 2011–12 has been relatively consistent (averaging 1129 t for all of GUR 1) and that red gurnard are mainly taken as bycatch, current catch levels are unlikely to compromise the long-term viability of this stock.

As the TACC is substantially higher than the current catch, it is not possible to evaluate potential impacts if catches increased to the level of the TACC.

Fishery Interactions

Red gurnard is taken on the west coast by bottom trawl targeted at snapper and trevally. Incidental captures of seabirds occur and there is a risk of incidental capture of Maui's dolphins.

• **GUR 1E**

Stock Status	
Year of Most Recent Assessment	2013
Assessment Runs Presented	Standardised CPUE
Reference Points	Target: B_{MSY} -compatible proxy based on the mean CPUE from 1995–96 to 2011–12 for the bottom trawl GUR 1 East (tow) series Soft Limit: 50% of target Hard Limit: 25% of target Overfishing threshold: F_{MSY}
Status in relation to Target	About as Likely as Not (40–60%) to be at or above B_{MSY}
Status in relation to Limits	Soft Limit: Unlikely (< 40%) Hard Limit: Very Unlikely (< 10%)
Status in relation to Overfishing	Unknown whether Overfishing is occurring

Historical Stock Status Trajectory and Current Status

Comparison of standardised CPUE for red gurnard in GUR 1E from models of catch rate in successful bottom trawl trips done for tow by tow data from 1995–96 (± 2 s.e.) and at stratum level including CELR data from 1989–90 (Kendrick & Bentley in prep. Also shown is the trajectory of total landed GUR 1 from the substock area. The two CPUE series have been scaled to the mean of each series for the years in common. Horizontal lines represent the target and the soft and hard limits.

RED GURNARD (GUR)

Annual relative exploitation rate for red gurnard in the GUR 1 east coast sub-stock.

Fishery and Stock Trends	
Recent Trend in Biomass or Proxy	The CPUE index fluctuates in a way that is consistent with the dynamics of a short lived species with variable recruitment, although the period is longer than that for other gurnard stocks. An increase from the lowest levels in 1995–96 was sustained over eight consecutive years, peaked in 2004–05 and has since declined to slightly below the target in 2011–12.
Recent Trend in Fishing Intensity or Proxy	Relative exploitation rate increased from 1989–90 to 1996–97, declined to 1998–99 and has since then fluctuated without trend below the long-term average.
Other Abundance Indices	The GUR 1 East (stratum) series is slightly longer than the GUR 1 East (tow) series, but has a similar trend for the overlapping period.
Trends in Other Relevant Indicators or Variables	-

Projections and Prognosis	
Stock Projections or Prognosis	Without information on recruitment, it is not possible to predict how the stock is going to respond in the next few years.
Probability of Current Catch or TACC causing decline below Limits	Soft Limit: Unknown Hard Limit: Unknown
Probability of Current Catch or TACC causing Overfishing to continue or to commence	Unknown if the catch remains at current levels Unknown whether catch at the level of the TACC would cause overfishing.

Assessment Methodology and Evaluation	
Assessment Type	Level 2 - Partial quantitative stock assessment
Assessment Method	Standardised CPUE based on positive catches from bottom trawl
Assessment Dates	Latest assessment: 2013 Next assessment: 2016
Overall assessment quality rank	1 – High Quality
Main data inputs (rank)	- Catch and effort data 1 – High Quality
Data not used (rank)	N/A
Changes to Model Structure and Assumptions	The accepted CPUE index is now a tow based index, rather than trip-stratum based.
Major Sources of Uncertainty	-

Qualifying Comments

As the red gurnard fishery in FMAs 1 and 9 has a long history, it is difficult to infer stock status from recent abundance trends. The abundance of all three sub-stocks appears to be cyclical, probably in response to recruitment variation, and in two sub-stocks trends are currently downward. This makes it difficult to predict future trends without recruitment information. Given that the catch levels observed from 1986–87 to 2011–12 has been relatively consistent (averaging 1129 t for all of GUR 1) and that red gurnard are mainly taken as bycatch, current catch levels are unlikely to compromise the long-term viability of this stock.

As the TACC is substantially higher than the current catch, it is not possible to evaluate potential impacts if catches increased to the level of the TACC.

Fishery Interactions

Red gurnard is taken as a bycatch on the east coast mainly by bottom longline targeted at snapper, with the balance taken almost equally by bottom trawl and Danish seine targeting snapper and John dory. Incidental captures of seabirds occur.

● **GUR 1 - BoP**

Stock Status	
Year of Most Recent Assessment	2013
Assessment Runs Presented	Standardised CPUE
Reference Points	Target: B_{MSY} -compatible proxy based on the mean CPUE from 1994–95 to 2011–12 for the bottom trawl GUR 1 BoP (tow) series Soft Limit: 50% of target Hard Limit: 25% of target Overfishing threshold: F_{MSY}
Status in relation to Target	About as Likely as Not (40–60%) to be at or above B_{MSY}
Status in relation to Limits	Soft Limit: Unlikely (< 40%) Hard Limit: Very Unlikely (< 10%)
Status in relation to Overfishing	Unknown whether Overfishing is occurring

Historical Stock Status Trajectory and Current Status

Comparison of standardised CPUE for red gurnard in GUR 1BoP from models of catch rate in successful bottom trawl trips done for tow by tow data from 1995–96 (± 2 s.e.) and at stratum level including CELR data from 1989–90 (Kendrick & Bentley in prep. Also shown is the trajectory of total landed GUR 1 from the substock area. The two CPUE series have been scaled to the mean of each series for the years in common. Horizontal lines represent the target and the soft and hard limits.

RED GURNARD (GUR)

Annual relative exploitation rate for red gurnard in the Bay of Plenty.

Fishery and Stock Trends	
Recent Trend in Biomass or Proxy	The CPUE index fluctuates in a way that is consistent with the dynamics of a short lived species with variable recruitment. An increase from the lowest levels in 1995–96 to a peak in 2000–01, and has since declined to slightly below the target in 2011–12.
Recent Trend in Fishing Mortality or Proxy	Relative exploitation rate has fluctuated without trend around the long-term mean since 1991–92
Other Abundance Indices	The GUR 1 BoP (stratum) series is slightly longer than the GUR 1 BoP (tow) series, but has a similar trend for the overlapping period.
Trends in Other Relevant Indicators or Variables	-

Projections and Prognosis

Assessment Methodology and Evaluation	
Assessment Type	Level 2 - Partial quantitative stock assessment
Assessment Method	Standardised CPUE based on positive catches from bottom trawl
Assessment Dates	Latest assessment: 2013 Next assessment: 2016
Overall assessment quality rank	1 – High Quality
Main data inputs (rank)	- Catch and effort data 1 – High Quality
Data not used (rank)	-
Changes to Model Structure and Assumptions	The accepted CPUE index is now a tow based index, rather than trip-stratum based.
Major Sources of Uncertainty	-

Qualifying Comments

As the red gurnard fishery in FMAs 1 and 9 has a long history, it is difficult to infer stock status from recent abundance trends. The abundance of all three sub-stocks appears to be cyclical, probably in response to recruitment variation, and in two sub-stocks trends are currently downward. This makes it difficult to predict future trends without recruitment information. Given that the catch levels observed from 1986–87 to 2011–12 has been relatively consistent (averaging 1129 t for all of GUR 1) and that red gurnard are mainly taken as bycatch, current catch levels are unlikely to compromise the long-term viability of this stock.

As the TACC is substantially higher than the current catch, it is not possible to evaluate potential impacts if catches increased to the level of the TACC.

Fishery Interactions

Red gurnard is taken as a bycatch in the Bay of Plenty mainly by bottom longline targeted at snapper, with the balance taken almost equally by bottom trawl and Danish seine targeting snapper and John dory. Incidental captures of seabirds occur.

• **GUR 2**

Stock Structure Assumptions

For the purpose of this summary GUR 2 is considered to be a single stock.

Stock Status	
Year of Most Recent Assessment	2014
Assessment Runs Presented	Standardised CPUE for BT.MIX
Reference Points	Target: B_{MSY} -compatible proxy based on the mean CPUE (BT(MIX)) for period 1990–91 to 2009–10 Soft Limit: 50% of target Hard Limit: 25% of target Overfishing threshold: F_{MSY}
Status in relation to Target	About as Likely as Not (40–60%) to be at or above the target
Status in relation to Limits	Soft Limit: Unlikely (< 40%) Hard Limit: Very Unlikely (< 10%)
Status in relation to Overfishing	Overfishing is Unlikely (< 40%) to be occurring (based on estimates of Z)

Historical Stock Status Trajectory and Current Status

Standardised catch per unit effort (CPUE) indices for GUR 2 from bottom trawling targeting gurnard, snapper and trevally (GUR.BT.MIX) that combines all form types at a daily aggregation, and for a shorter time series that uses only tow based data (Kendrick & Bentley in prep). Scaling is relative to the years in common. In both standardisation models, a gamma error distribution was assumed. Horizontal lines are the target and the soft limits.

RED GURNARD (GUR)

Fishery and Stock Trends	
Recent Trend in Biomass or Proxy	CPUE indices declined between 1990 and 1998 and then fluctuated without trend until 2012, with an increase in 2013. Standardised CPUE in 2012-13 is above the target.
Recent Trend in Fishing Mortality or Proxy	Relative exploitation rate increased gradually from 1989/90 to 2009/10 and then dropped to the long-term average by 2012/13.
Other Abundance Indices	Tow based analysis of 2007-08 to 2012-13 data closely resembles the mixed form type analysis. CPUE index (BT.TAR) has also followed similar trends to the CPUE BT.MIX index.
Trends in Other Relevant Indicators or Variables	Catch curve analysis indicated that fishing mortality was at or below M in 2010 (depending on the age at full recruitment).

Projections and Prognosis	
Stock Projections or Prognosis	Without information on recruitment, it is not possible to predict how the stock is going to respond in the next few years.
Probability of Current Catch or TACC causing decline below Limits	Soft Limit: Unlikely (<40%) Hard Limit: Very Unlikely (<10%) Unknown whether catch at the level of the TACC would cause decline below both the soft and hard Limits.
Probability of Current Catch or TACC causing Overfishing to continue or to commence	Probability of TACC causing overfishing to occur or commence: Unlikely if the catch remains at the average of 2000–2013 levels. Unknown whether catch at the level of the TACC would cause overfishing.

Assessment Methodology and Evaluation		
Assessment Type	Level 2 - Partial quantitative stock assessment	
Assessment Method	1. Standardised CPUE. 2. Estimates of total mortality (Z) using Chapman-Robson Estimator	
Assessment Dates	Latest assessment: 2014	Next assessment: 2017
Overall assessment quality rank	1 – High Quality	
Main data inputs (rank)	- Catch and effort data - Catch-at-age	1 – High Quality 1 – High Quality
Data not used (rank)	N/A	
Changes to Model Structure and Assumptions	- Gamma instead of lognormal error structure for CPUE analysis	

Major Sources of Uncertainty	- Uncertainty in estimate of M
------------------------------	--------------------------------

Qualifying Comments
As the TACC is substantially higher than the current catch, it is not possible to evaluate potential impacts if catches increased to the level of the TACC.

Fishery Interactions
Red gurnard is taken in FMA 2 by the bottom trawl fishery targeting snapper, gurnard and trevally and as a bycatch in bottom trawl fisheries targeting flatfish and tarakihi. Incidental captures of seabirds occur and there is a risk of incidental capture of Hector's dolphins at the southern end of the QMA.

● **GUR 3**

Stock Structure Assumptions

No information is available on the stock separation of red gurnard. The Fishstock GUR 3 is treated in this summary as a unit stock.

Stock Status	
Year of Most Recent Assessment	2014
Reference Points	Target: B_{MSY} -compatible proxy based on CPUE is twice the soft limit. Soft Limit: Mean from 1997–98 to 1999–00 of BT(MIX+FLA) series, as defined in Starr & Kendrick (2012) Hard Limit: 50% of soft limit Overfishing threshold: F_{MSY}
Status in relation to Target	Likely (> 60%) to be above the target
Status in relation to Limits	Soft Limit: Very Unlikely (< 10%) to be below Hard Limit: Very Unlikely (< 10%) to be below
Status in relation to Overfishing	About as Likely as Not (40-60%) to be overfishing Catch/CPUE ratio in 2011/12 and 2012/13 comparable to level from 1989/90-2007/08.

Fishery and Stock Trends	
Recent Trend in Biomass or Proxy	Two bottom trawl CPUE series (one targeted at flatfish and the other at red cod), which are considered to be an index of stock abundance, increased steadily from the late 1990s to 2009/10, and then declined, remaining above the target level. The resumed east coast South Island trawl survey has returned four biomass indices in 2007, 2008, 2009 and 2012 which are greater than equivalent estimates from the early 1990s.

Recent Trend in Fishing Mortality or Proxy	Catch/CPUE ratio in 2011/12 and 2012/13 comparable to level from 1989/90-2007/08.
--	---

Historical Stock Status Trajectory and Current Status

East coast South Island winter trawl survey, CPUE, Catch and TACC Trajectories

Comparison of east coast South Island winter trawl survey recruited biomass and CPUE indices (average FLA and MIX) and the trajectories of catch and TACCs from 1989–90 to 2012–13. The horizontal grey line represents the MSY proxy relative to the CPUE series.

Other Abundance Indices	ECSI summer survey - not used
Trends in Other Relevant Indicator or Variables	-

Projections and Prognosis	
Stock Projections or Prognosis	Quantitative stock projections are unavailable.
Probability of Current Catch or TACC causing Biomass to remain below or to decline below Limits	Soft Limit: Unlikely (< 40%) Hard Limit: Very Unlikely (< 10%) Current abundance is at historically high levels and is unlikely to decline below limits in 3-5 years
Probability of Current Catch or TACC causing Overfishing to continue or to commence	GUR is mostly taken as a bycatch (about 10% targeted). The correspondence between relative abundance and catch suggests a constant exploitation rate. The current catch is therefore Unlikely (< 40%) to cause overfishing.

Assessment Methodology and Evaluation	
Assessment Type	Level 2: Partial Quantitative Stock Assessment
Assessment Method	Agreed standardised CPUE series and trawl survey biomass indices
Period of Assessment	Latest assessment: 2014 Next assessment: 2017
Overall assessment quality rank	1 – High Quality
Main data inputs (rank)	-Trawl survey biomass indices and associated length frequencies - Catch and effort data
	1– High Quality 1– High Quality
Data not used (rank)	N/A

Changes to Model Structure and Assumptions	-
Major Sources of Uncertainty	Prior to 2007 the ECSI trawl survey did not cover the entire depth range for red gurnard.

Qualifying Comments

Red gurnard are relatively short-lived and reasonably productive. They exhibit strong interannual fluctuations and were at apparent low levels in the mid-1990s. Stock size appears to have increased substantially since then and commercial fishers indicate that they find it difficult to stay within the TACC despite the low level of targeting on this species.

Two independent CPUE series and the trawl survey corroborate that stock size for GUR 3 has increased since the late 1990s.

There are potentially enough data to undertake a quantitative stock assessment for GUR 3. This would allow the estimation of B_{MSY} and other reference points.

Fishery Interactions

Red gurnard in GUR 3 are taken almost entirely by bottom trawl in fisheries targeted at red cod, barracouta and flatfish. Some gurnard are also taken in the target tarakihi and stargazer bottom trawl fisheries. The level of targeting on this species is low, averaging less than 10% of the total landed catch since 1989–90.

Incidental captures of seabirds occur and there is a risk of incidental capture of Hector's dolphins.

● **GUR 7**

Stock Structure Assumptions

Stock boundaries are unknown, but for the purpose of this summary, GUR 7 is considered to be a single management unit.

Biomass trends differ between the west coast South Island and Tasman Bay/Cook Strait areas; however, the former area accounts for the largest proportion of the catch (about 65% in recent years). Because the WG has discounted the value of both CPUE series from TBGB, and the TBGB trawl survey indices are skewed towards juveniles, advice for GUR 7 is largely based on abundance indices for the west coast portion of the QMA.

Stock Status	
Year of Most Recent Assessment	2013 (West Coast South Island trawl survey); 2014 CPUE analysis
Reference Points	Target1: B_{MSY} -compatible proxy based on the WCSI Trawl Survey is the mean from 1992 to 2013 for the west coast region. Target2: B_{MSY} -compatible proxy based on CPUE is the mean from 1989–90 to 2012/13 of the average BT(MIX+FLA) west coast series, as defined in Langley (2014). Soft Limit: 50% Target Hard Limit 25% Target Overfishing threshold: F_{MSY}
Status in relation to Target	About as Likely as Not (40–60%) to be at or above the target
Status in relation to Limits	Soft limit: Unlikely (< 40%) to be below Hard Limit: Very Unlikely (< 10%) to be below
Status in relation to Overfishing	Overfishing is Unlikely (< 40%) to be occurring
Fishery and Stock Trends	
Trend in Biomass or Proxy	The West Coast South Island trawl survey relative biomass indices from 2011 and 2013 were the highest of the entire time series. WCSI CPUE indices increased steadily from 2009/10 to 2012/13;

RED GURNARD (GUR)

	CPUE indices for the Tasman Bay fishery also remained high in recent years.
Trend in Fishing Mortality or Proxy	Unlikely (< 40%) that overfishing is occurring. Biomass has increased considerably since 2009/10 while there was only a moderate increase in annual catches.

Historical survey biomass, Catch and TACC Trajectories

Standardised CPUE indices for GUR 7 from a composite west coast inshore trawl fishery index series (top panel), and WCSI trawl survey biomass indices for recruited (≥ 28 cm T.L.) red gurnard in the west coast area (bottom Panel). The vertical bars represent the associated 95% confidence intervals for the trawl survey. The GUR 7 annual catches and TACCs are also presented.

Other Abundance Indices	-
Trends in Other Relevant Indicators or Variables	Estimates of pre-recruit fish from the Challenger trawl survey indicate moderate recruitment in recent years. These year classes will continue to sustain the commercial fishery over the next few years.
Projections and Prognosis	
Stock Projections or Prognosis	Recent catches and the TACC are likely to be sustainable, at least in

	the short-term. Quantitative stock projections are unavailable.
Probability of Current Catch or TACC causing Biomass to remain below or to decline below Limits	Soft Limit: Unlikely (< 40%) Hard Limit: Very Unlikely (< 10%) Current abundance is at historically high levels and is unlikely to decline below limits in 3-5yrs
Probability of Current Catch or TACC causing Overfishing to continue or to commence	Unlikely (< 40%)

Assessment Methodology and Evaluation		
Assessment Type	Level 2: Partial Quantitative Stock Assessment	
Assessment Method	West Coast South Island trawl survey biomass - Survey length frequency - Standardised CPUE indices	
Assessment Dates	Latest assessment: 2014	Next assessment: 2015
Overall assessment quality rank	1 – High Quality	
Main data inputs	- Survey biomass and length frequencies - CPUE indices	1 – High Quality 1 – High Quality
Changes to Model Structure and Assumptions	-	
Major Sources of Uncertainty	-	

Qualifying Comments
Red gurnard are a survey target of the West Coast South Island trawl survey and the Southern Inshore Working Group regards the series as a reliable index of abundance. Trends in CPUE indices are not consistent with trends in trawl survey biomass. The selectivity of the commercial fishery is unknown and it is unknown whether the two sets of indices are monitoring the same component of the stock. However, the CPUE indices for a mixed target species bottom trawl fishery and the flatfish target bottom trawl fishery have similar trends and have been averaged to obtain a composite series.

Fishery Interactions
Red gurnard are primarily taken in conjunction with the following QMS species: barracouta, stargazer, red cod, tarakihi and other species in the West Coast South Island arget bottom trawl fishery. Incidental captures of seabirds occur and there is a risk of incidental capture of Hector's dolphins.

• **GUR 8**

It is not known if recent catch levels or the current TACC are sustainable. Yields estimates, TACCs, and reported landings for red gurnard for the most recent year are summarised in Table 8.

Table 8: Summary of yield estimates (t), TACCs (t) and reported landings (t) of red gurnard for the most recent fishing year.

Fishstock	QMA	FMA	2012–13 Actual TACC	2012–13 Reported landings
GUR 1	Auckland (GUR 1W & GUR 1E)	1 & 9	2 288	1 103
GUR 2	Central (east)	2	725	603
GUR 3	South-East, Southland and Sub-Antarctic	3, 4, 5, & 6	1 100	1 168
GUR 7	Challenger	7	785	763
GUR 8	Central (west)	8	543	170
GUR 10	Kermadec	10	10	0
Total			5 451	3 807
